1. **Scope**

Environmental noise from various sound sources such as roads, railways, air traffic, and industrial plants depends on the generation and propagation of sound. There exist methods for determining the sound power levels emitted by various noise sources. This Nordtest method specifies a calculation method for the prediction of the attenuation of noise during propagation outdoors.

The method described is general in the sense that it may be applied to a wide variety of noise sources, and covers most of the major mechanisms of attenuation. There are, however, constraints on its use, which arise principally from the description of environmental noise. The prediction method can be used for predicting the effect of propagation of noise in one-third octave bands from 25 Hz to 10 kHz when sound is propagating over ground from a point source to a receiver. More complex sources can be represented by collections of incoherent point sources.

The method can be used as one component in a method for the calculation of the EU noise indicators $L_{den}$ and $L_{night}$ and the production of noise mappings.

2. **Field of Application**

The method can be used for any normally occurring terrain shapes, and for a class of typical weather conditions. For noise sources close to the ground, such as roads and railways, the method can be used for propagation up to approximately 1 km. For high noise sources, e.g. wind turbines and airborne aircraft, the method can be used for propagation up to several kilometers.

The method predicts the effect of typical weather conditions on noise levels, and hence the method can be used for prediction of the yearly average noise levels. This includes the EU indicators $L_{den}$ and $L_{night}$.

The method is valid for weather conditions where the vertical effective sound speed profile can be approximated by the so-called log-lin profile. Many typical weather conditions can be approximated by a log-lin profile with a good accuracy. This includes neutral as well as stably and unstably stratified atmospheres. The method cannot be expected to work well for special layered atmospheres. This imposes a limitation on the range of propagation since long-range propagation may include cases with more complicated layered atmospheres.

The calculation is valid for a point source. Most real noise source cannot be considered a point source. Therefore these sources normally have to be divided in a number of incoherent sub-sources as described in related methods for determining the sound power levels emitted by various noise sources.
The method is based on a simplified terrain description defined by a number of straight line segments, and therefore denoted a segmented terrain. The simplification of a real terrain into the segmented terrain is not included in the Nordtest method, but guidelines are included. The segmented terrain includes natural terrain, but also other obstacles such as buildings and noise barriers.

The geometry in the method is in general two-dimensional. The only exception from this rule is the case of reflection from vertical objects where the size of the reflector lateral to the propagation path has to be considered. This implies that the terrain shape and weather conditions are assumed to be constant perpendicular to the direction of propagation. The production of noise mappings must include three-dimensional effects, and in particular reflections from vertical obstacles. Reflections may contribute significantly to the sound pressure level at the receiver, particularly if the direct propagation path is blocked by obstacles. This is the reason why this 3D effect is included in the method while others have been left out. The Annex gives informative guidelines on how to include lateral diffraction around finite screens.

Due to the assumption in the basic method, screens are in principle assumed to have infinite horizontal length perpendicular to the direction of propagation. However, if a screen has a finite horizontal size a significant contribution of sound may propagate laterally from source to receiver around the vertical edges of the screen. Other three-dimensional effect from variation in terrain shape and surface conditions outside the propagation path may occur, and can be taken into account by similar ideas.

It is assumed that the terrain surface properties can be described by the Delany and Bazley impedance model. This model works well for many ground surfaces, but less well for some important special surfaces including porous asphalt. The use of other impedance model in the prediction method for such surfaces has shown acceptable results in some cases after a modification of the method. The use of other impedance models is not included in the method, and requires separate consideration for each particular case.

A complete definition of the input quantities and the effects included in the calculation is given in Section 4.

3. **Normative References**

The following standards contain provisions which, through reference in this text, constitute provisions of this method. At the time of publication, the editions indicated were valid. All standards are subject to revision, and parties to agreements based on this method are encouraged to investigate the possibility of applying the most recent edition of the standards indicated below. Members of IEC and ISO maintain registers of currently valid international standards.
ISO 266:1997, *Acoustics - Preferred frequencies*

4. **Definitions**

4.1 **Conventions**

\[ \hat{\xi} \] The symbol \( \hat{\cdot} \) placed over a variable indicates that the variable is a complex number.

\[ \tilde{z} \] The symbol \( \ast \) indicates the complex conjugate

\[ \bar{\xi} \] The symbol \( \cup \) placed over a variable indicates that the variable is refraction corrected (in case of refraction the geometry has been transformed into an equivalent geometry corresponding to non-refracting propagation)

\[ \oplus \] The symbol \( \oplus \) indicates energy summation of noise levels (incoherent summation):

\[ L_1 \oplus L_2 = 10 \log \left( 10^{L_1/10} + 10^{L_2/10} \right) \]

**NA** \( NA \) or \( na \) means Not Applied and is used where a value is not applied (may be a value in a two-dimensional table or a value returned by a function)

\[ \log \] The function \( \log \) used in equations means the logarithm to the base 10

\[ \ln \] The function \( \ln \) used in equations means the natural logarithm (base \( e \))

4.2 **Variables**

\( a \) Mean stem radius, forest (m)

\( A \) Coefficient of the logarithmic part of the sound speed profile (m/s)
$A_+ \quad$ Upper limit of $A$ $(= A + 1.7 s_A)$ (m/s)

$B \quad$ Coefficient of the linear part of the sound speed profile $(s^{-1})$

$B_+ \quad$ Upper limit of $B$ $(= B + 1.7 s_B)$ $(s^{-1})$

$C_v^2 \quad$ Structure parameter of turbulent wind speed fluctuations $(m^{4/3}s^{-2})$

$C_T^2 \quad$ Structure parameter of turbulent temperature fluctuations $(Ks^{-2})$

$c \quad$ Sound speed (m/s)

$\bar{c} \quad$ Average sound speed between the heights $h_S$ and $h_R$ above the ground (m/s)

$c_0 \quad$ Sound speed at the ground in equivalent linear sound speed profile (m/s)

$d \quad$ Distance from source to receiver measured along flat terrain (m)

$d_{\text{segm}} \quad$ Length of project of segment onto terrain baseline (m)

$d_{SZ} \quad$ Distance from source to shadow zone measured along terrain segment (m)

$d_{\text{refl}} \quad$ Distance from source to reflection point measured along terrain segment (m)

$d' \quad$ Distance between projection of S and R onto a terrain segment (m)

$d_{r,l} \quad$ Distance from reflection point to left edge of reflector (m)

$d_{r,r} \quad$ Distance from reflection point to right edge of reflector (m)

$f \quad$ Frequency (Hz)

$F_f \quad$ Coherence coefficient due to frequency band averaging

$F_{\Delta\tau} \quad$ Coherence coefficient due to fluctuating refraction

$F_c \quad$ Coherence coefficient due to turbulence

$F_r \quad$ Coherence coefficient due to terrain surface roughness

$F_s \quad$ Coherence coefficient due to propagation through scattering zones
$F_{\lambda}$ Fraction of the wavelength in Fresnel zone calculations

$h_R$ Shortest distance from receiver to terrain (m)

$h_{Rv}$ Height of receiver vertically above terrain (m)

$h'_R$ Height of R above a terrain segment (m)

$h_s$ Shortest distance from source to terrain (m)

$h_{sv}$ Height of source vertically above terrain (m)

$h'_s$ Height of S above a terrain segment (m)

$h_{SCR}^*$ Artificial height over screen used when determining the equivalent linear sound speed profile (m)

$j$ Complex unit

$k$ Wave number (m$^{-1}$)

$k_0$ Wave number at the ground corresponding to $c_0$ (m$^{-1}$)

$L_W$ Sound power level (dB)

$M$ Indicates middle part as suffix (between screens or screen edges)

$n^*$ Density of stems, forest (m$^{-2}$)

$n_{xz}$ Number of points in the terrain (= $N_{ts} + 1$)

$N_{ts}$ Number terrain segments

$\hat{p}$ Sound pressure with amplitude and phase (complex number)

$\hat{Q}$ Spherical wave reflection coefficient

$r$ Ground roughness (m)

$R$ Indicates receiver as suffix

$R$ Travel distance (m)
\( R_{A,B} \)  Radius of curvature of ray path (m)

\( RH \)  Mean relative humidity along propagation path, used for air absorption (\%)

\( \Re_i \)  Incoherent reflection coefficient based on \( \alpha_i \)

\( \hat{\Re}_p \)  Plane wave reflection coefficient

\( S \)  Indicates source as suffix

\( s_A \)  Standard deviation of \( A \) from short-term meteorological fluctuations (m/s)

\( s_B \)  Standard deviation of \( B \) from short-term meteorological fluctuations (s\(^{-1}\))

\( t_0 \)  Temperature at the ground (°C)

\( t_{\text{mean}} \)  Mean temperature between the heights \( h_S \) and \( h_R \) above the ground (°C)

\( t_{\text{air}} \)  Mean temperature along propagation path, used for air absorption (°C)

\( T \)  Edge point of screen

\( T_1 \)  Edge closest to source

\( T_2 \)  Edge closest to receiver

\( w \)  Fresnel-zone weight

\( x \)  Horizontal position of a ground point (m)

\( z \)  Vertical position of a ground point (m)

\( z_{r,\text{upp}} \)  Height of upper edge of reflector (m)

\( z_{r,\text{low}} \)  Height of lower edge of reflector (m)

\( z_0 \)  Roughness length (m)

\( \hat{Z}_G \)  Normalized ground impedance

\( \alpha \)  Absorption coefficient
\( \alpha_{ri} \)  Random incidence absorption coefficient

\( \beta \)  Wedge angle (radians)

\( \Delta L_d \)  Propagation effect of spherical divergence of the sound energy (dB)

\( \Delta L_a \)  Propagation effect of air absorption (dB)

\( \Delta L_t \)  Propagation effect of terrain (ground and barriers) (dB)

\( \Delta L_s \)  Propagation effect of scattering zones (dB)

\( \Delta L_r \)  Propagation effect of reflection by an obstacle (dB)

\( \Delta \theta \)  Change in ray angle (radians)

\( \Delta \tau \)  Travel time difference for average refraction (s)

\( \Delta \tau_u \)  Travel time difference for upper refraction (s)

\( \theta_R \)  Diffraction angle of a wedge, receiver side (radians)

\( \theta_S \)  Diffraction angle of a wedge, source side (radians)

\( \theta_r \)  Reflection angle between direction from image source \( S' \) to receiver \( R \) and direction of the reflector (radians)

\( \lambda \)  Wavelength (m)

\( \lambda_0 \)  Wavelength at the ground corresponding to \( c_0 \) (m)

\( \xi \)  Relative sound speed gradient (m\(^{-1}\))

\( \xi_{ray} \)  Relative sound speed gradient corresponding to \( R_{A,B} \) (m\(^{-1}\))

\( \rho \)  Transversal separation between rays (m)

\( \rho_E \)  Effective energy reflection coefficient \( \rho_E \) of a reflector

\( \sigma \)  Ground flow resistivity (Pasm\(^{-2}\))

\( \tau \)  Travel time for average refraction (s)

\( \tau_u \)  Travel time for upper refraction(s)
4.3 Coordinates

\( O = (x_O, z_O) \) \quad \text{Reflection point coordinates at vertical reflector}

\( P_S = (x_{SGv}, z_{SGv}) \) \quad \text{Ground point vertically below source}

\( P_R = (x_{RGv}, z_{RGv}) \) \quad \text{Ground point vertically below receiver}

\( R = (x_R, z_R) \) \quad \text{Receiver coordinates}

\( R_G = (x_{RG}, z_{RG}) \) \quad \text{Ground point closest to receiver}

\( S = (x_S, z_S) \) \quad \text{Source coordinates}

\( S_G = (x_{SG}, z_{SG}) \) \quad \text{Ground point closest to source}

\( T = (x_T, z_T) \) \quad \text{Coordinates of screen edge T}

\( T_1 = (x_{T1}, z_{T1}) \) \quad \text{Coordinates of screen edge T_1}

\( T_2 = (x_{T2}, z_{T2}) \) \quad \text{Coordinates of screen edge T_2}

4.4 Auxiliary Functions

In order to simplify the description of the method a number of the auxiliary functions have been defined. Most of the functions are described in Section 5.23 where the paragraph headlines correspond to the names of the functions. Other auxiliary functions have been described in different sections throughout the Nordtest standard method. These functions are summarized in Section 5.23.20 with a reference to the section where they have been described.

5. Calculation Method

5.1 Introduction

The method described in Section 5 predicts the attenuation of sound propagating over ground outdoors from a point source to a receiver. The sound pressure level at the receiver is predicted in one-third octave bands from 25 Hz to 10 kHz. The calculated sound pressure levels are short term levels such as instantaneous sound pressure levels or equivalent...
sound pressure level over a time period without a change in the weather. Short term equivalent sound pressure levels normally have duration of no more than a few hours.

In the method it is assumed that the two-dimensional terrain profile is approximated by a number of straight line segment and that screen and other man-made structure have been made a part of the terrain profile.

In the description of the method a number of auxiliary functions are used which are described in Section 5.23.

5.2 Structure of the Prediction Method

The sound pressure level $L_R$ at the receiver is for each frequency band predicted according to Eq. (1). The equation is used for a direct propagation path from source to receiver as well as for a reflection path via a reflection point.

$$L_R = L_W + \Delta L_d + \Delta L_a + \Delta L_t + \Delta L_s + \Delta L_r$$  \hspace{1cm} (1)

where

$L_W$ is the sound power level within the considered frequency band,

$\Delta L_d$ is the propagation effect of spherical divergence of the sound energy,

$\Delta L_a$ is the propagation effect of air absorption,

$\Delta L_t$ is the propagation effect of the terrain (ground and screens),

$\Delta L_s$ is the propagation effect of scattering zones,

$\Delta L_r$ is the propagation effect of obstacle dimensions and surface properties when calculating a contribution from sound reflected by an obstacle. If the ray path is not a reflection path $\Delta L_r = 0$.

The propagation effects mentioned above are assumed to be independent and can therefore be predicted separately. The only exception is the effect of the terrain $\Delta L_t$ and the effect of scattering zones $\Delta L_s$ which may interact to some extent as a decrease in coherence introduced by the latter effect may affect the prediction of the former.

5.3 Definition of Input Variables

The input variables can be divided in variables defining the terrain and the weather variables and optionally variables defining a scattering zone.
5.3.1 Terrain Definition Variables

The simplified terrain is defined by the coordinates \((x,z)\) of the points of discontinuity in the terrain profile and the flow resistivity \(\sigma\) and ground roughness \(r\) of each terrain segment as shown in Table 1. The number of points in the profile is denoted \(nxz\) and the profile therefore contains \(N_{ts} = nxz - 1\) segments. In the present Nordtest method the x-coordinates has to be in ascending order \((x_i > x_{i-1})\). The numbering of the segments in the terrain profile is from 1 to \(N_{ts}\). Therefore, segment no. \(i\) has the end coordinates \((x_i, z_i)\) and \((x_{i+1}, z_{i+1})\) and flow resistivity \(\sigma_i\) and ground roughness \(r_i\). The terrain defined by Table 1 is sometimes denoted a segmented terrain.

*Table 1*

Terrain profile definition.

The position of the point source \(S\) and the receiver \(R\) are defined by the vertical source and receiver heights \(h_S\) and \(h_R\). \(h_S\) is the height of \(S\) above the first point \((x_1, z_1)\) in the terrain profile and \(h_R\) is the height above the last point \((x_{nxz}, z_{nxz})\).

5.3.2 Weather Definition Variables

The input variables defining the weather condition are:

- \(z_0\) Roughness length (m)
- \(A\) Coefficient of the logarithmic part of the sound speed profile (m/s)
- \(B\) Coefficient of the linear part of the sound speed profile (s\(^{-1}\))
- \(s_A\) Standard deviation of \(A\) from short-term meteorological fluctuations (m/s)
- \(s_B\) Standard deviation of \(B\) from short-term meteorological fluctuations (s\(^{-1}\))
- \(t_0\) Temperature at the ground (°C)
\( C_v^2 \)  Structure parameter of turbulent wind speed fluctuations (m\(^{4/3}\)s\(^{-2}\))

\( C_T^2 \)  Structure parameter of turbulent temperature fluctuations (Ks\(^{-2}\))

\( t_{\text{air}} \)  Mean temperature along propagation path, used for air absorption (°C)

\( RH \)  Mean relative humidity along propagation path, used for air absorption (%)

The variables above defines the vertical effective sound speed profile \( c(z) \) as shown in Eq. (2) where \( z \) is the height above the ground surface and \( C \) is the sound speed at the ground determined using the auxiliary function \( Coft \) as shown in Eq. (3). To avoid numerical problems in the calculation of sound rays (Section 5.5) when \( z_0 \) becomes less than 0.001 m, it is recommended to use the value 0.001 m. In the following the effective sound speed will simply be designated the sound speed. In case of segmented terrain \( z \) is the perpendicular (slant) distance to each segment.

\[
c(z) = A \ln \left( \frac{z}{z_0} + 1 \right) + B z + C \tag{2}
\]

\[
C = Coft(t_0) \tag{3}
\]

\( s_A \) and \( s_B \) include short term fluctuations (without a significant change in the weather) in the sound speed profile in excess what is already covered by the structure parameters \( C_v^2 \) and \( C_T^2 \). Therefore, when calculating instantaneous noise levels \( s_A \) and \( s_B \) shall be zero.

The weather coefficients \( A \) and \( B \) are determined from weather data available at normal weather stations. When calculating the yearly average of noise levels according to [4] \( A \) and \( B \) are directly used to describe the different meteorological classes in [4].

### 5.3.3 Scattering Zone Variables

The forest (or other kind of dense vegetation) is defined by the following variables.

\( x_{i,1} \)  X-coordinate of the beginning of belt no. \( i \)

\( x_{i,2} \)  X-coordinate of the end of belt no. \( i \)

\( a \)  Mean stem radius

\( n^* \)  Density of stems

\( \alpha \)  Effective absorption coefficient of stems
Average height of trees

It is required that $x_{i,1} < x_{i,2} < x_{i+1,1}$. If the belt of trees from a propagation point of view has a limited width perpendicular to the direction of propagation information on the width (in the Y-coordinate direction) has to be included as described in Section 5.19.

### 5.3.4 Reflection Path Variables

The propagation effect of a reflection path is predicted by the same propagation model used for the direct path on basis of the propagation parameters defined in Sections 5.3.1 to 5.3.3 determined along the reflection path. However, the propagation effects in Eq. (1) will also include a propagation effect $\Delta L_r$ which is a correction for the efficiency of the reflection. The reflection path is shown in Figure 1.

For a reflection path separate weather coefficient A and B are given before and after the reflection point and additional input variables are included to define size, orientation and surface properties of the reflector:

- $A_1$ Weather coefficient A before reflection point (m/s)
\[ A_2 \quad \text{Weather coefficient A after reflection point (m/s)} \]
\[ B_1 \quad \text{Weather coefficient B before reflection point (s}^{-1}\text{)} \]
\[ B_2 \quad \text{Weather coefficient B after reflection point (s}^{-1}\text{)} \]
\[ d_1 \quad \text{Distance from source to reflection point (m)} \]
\[ d_2 \quad \text{Distance from reflection point to receiver (m)} \]
\[ z_{r,up} \quad \text{Height of upper edge of reflector (m)} \]
\[ z_{r,low} \quad \text{Height of lower edge of reflector (m)} \]
\[ d_{r,l} \quad \text{Distance from reflection point to left edge of reflector (m)} \]
\[ d_{r,r} \quad \text{Distance from reflection point to right side of reflector (m)} \]
\[ \theta_r \quad \text{Angle between direction from image source S’ to receiver R and direction of reflector (radians)} \]
\[ \rho_E \quad \text{Effective energy reflection coefficient } \rho_E \text{ of reflector} \]

### 5.4 Definition of Auxiliary Variables

#### 5.4.1 Terrain Definition Variables

The first and the last point in the input terrain profile defined in Section 5.3.1 are also denoted \( P_S = (x_{SGv}, z_{SGv}) \) and \( P_R = (x_{RGv}, z_{RGv}) \) as shown in Eq. (4).

\[
P_S = (x_{SGv}, z_{SGv}) = (x_1, z_1) \\
P_R = (x_{RGv}, z_{RGv}) = (x_{rz}, z_{rz})
\]  \( \text{(4)} \)

The position of the point source \( S = (x_S, z_S) \) and the receiver \( R = (x_R, z_R) \) are defined by the vertical source and receiver heights \( h_{Sy} \) and \( h_{Ry} \). \( h_{Sy} \) is the height of \( S \) above \( P_S \) and \( h_{Ry} \) is the height of \( R \) above \( P_R \). If the heights \( h_{Sy} \) or \( h_{Ry} \) are less than 0.01 m this value is used instead.

The position of \( S \) and \( R \) are therefore as shown in Eq. (5).
\[
\begin{align*}
S &= (x_S, z_S) = (x_1, z_1 + h_S) \\
R &= (x_R, z_R) = (x_{nz}, z_{nz} + h_R)
\end{align*}
\] (5)

Outside the defined terrain profile the surface is assumed to continue with the same slope as the nearest segment.

The source height \(h_S\) is defined as the distance from \(S\) to the source ground point \(S_G = (x_{SG}, z_{SG})\) and the receiver height \(h_R\) as the distance from \(R\) to the receiver ground point \(R_G = (x_{RG}, z_{RG})\), where \(S_G\) and \(R_G\) are the points on the terrain closest to \(S\) and \(R\), respectively. The points \(S_G\) and \(R_G\) and the heights \(h_S\) and \(h_R\) can be determined by Eqs. (6) and (7) using the auxiliary function \(\text{NormLine}\).

\[
\begin{align*}
(x_{SG}, z_{SG}, h_S) &= \text{NormLine}(x_1, z_1, x_2, z_2, x_S, z_S) \\
(x_{RG}, z_{RG}, h_R) &= \text{NormLine}(x_{nz-1}, z_{nz-1}, x_{nz}, z_{nz}, x_R, z_R)
\end{align*}
\] (6) (7)

The definition of points \(S, R, S_G, S_R, P_S,\) and \(P_R\) is illustrated in Figure 2 which also shows the terrain baseline defined as the line \(P_S P_R\).

\[\text{Figure 2}\]

Definition of source points and source ground points.

In the calculation procedure it is required that the terrain is defined from the source ground point \(S_G\) to the receiver ground point \(R_G\). Therefore, if \(x_{SG} < x_1 (x_1, z_1)\) in the terrain profile shall be replaced by \((x_{SG}, z_{SG})\). Likewise, if \(x_{RG} > x_{nz} (x_{nz}, z_{nz})\) shall be replaced by \((x_{RG}, z_{RG})\).

The source-receiver distance \(R_{SR}\) and the length of the terrain baseline can now be determined used the auxiliary function \(\text{Length}\) as shown in Eqs. (8) and (9).
\[ R_{SR} = \text{Length}(x_S, z_S, x_R, z_R) \]  
\[ d_{\text{base}} = \text{Length}(x_{SGV}, z_{SGV}, x_{RGV}, z_{RGV}) \]

A number of variables are used to define the properties of each point of discontinuity (index \( i \)) in the terrain profile. These are:

- \( d_{\text{base}}(i) \): Distance between \( P_S = (x_{SGV}, z_{SGV}) \) and the projection of point no. \( i \) onto terrain baseline \( (d_{\text{base}}(n_{xz}) = d_{\text{base}}) \)
- \( h_{\text{base}}(i) \): Shortest distance of terrain point \( i \) to terrain baseline

A number of variables are used to define the properties of each segment (index \( i \)) in the terrain profile. These are:

- \( h_S'(i) \): Height of \( S \) above segment \( i \)
- \( h_R'(i) \): Height of \( R \) above segment \( i \)
- \( d'(i) \): Distance between projection of \( S \) and \( R \) onto segment \( i \)
- \( d_{\text{segm}}(i) \): Length of projection of segments onto terrain baseline

### 5.4.2 Weather Definition Variables

When the weather coefficient \( A \) and \( B \) are fluctuating \((s_A > 0 \text{ and } s_B > 0)\) upper values of \( A \) and \( B \) denoted \( A_+ \) and \( B_+ \) are determined as shown in Eq. (10).

\[
A_+ = A + 1.7s_A \\
B_+ = B + 1.7s_B
\]  

(10)

The variable \( t_{\text{mean}} \) is defined as the average temperature between the height \( h_S \) and \( h_R \) above the ground.

### 5.4.3 Definition of One-Third Octave Band Centre Frequencies

The centre frequencies of each of the 27 one-third octave bands are determined by Eq. (11).

\[
bno = 1, 2, \ldots, 27 \\
f(bno) = 10^{\frac{bno+13}{10}}
\]  

(11)
5.4.4 Wavelength and Wave Number at the Ground

The wavelength $\lambda_0$ and wave number $k_0$ at the ground are in Eq. (13) and (14) defined on basis of the sound speed $c_0$ at the ground in the equivalent linear sound speed profile calculated as shown in Eq. (12) by the function $CalcEqSSP$ described in Section 5.5.2.

$$\left(NA, c_0, NA\right) = CalcEqSSP(h_{sv}, h_{rv}, z_0, A, B, C)$$  \hspace{1cm} (12)

$$\lambda_0 = \frac{c_0}{f}$$  \hspace{1cm} (13)

$$k_0 = \frac{2\pi f}{c_0}$$  \hspace{1cm} (14)

5.5 Sound Rays and Ray Variables

The calculation of the propagation effect is based on concept of sound rays and the basic approach in the sub-models are to calculate the sound pressure for each ray and add the pressure of all rays to obtain the total sound pressure. In sub-models without screens the rays go from source to receiver and in sub-models with screen from source to receiver via the screen tops. Figure 3 through Figure 6 show examples of such rays in case of downward refraction (the sound speed is increasing with the height) and in case of upward refraction (the sound speed is decreasing with the height).

![Sound rays for flat terrain in case of downward refraction.](image)

**Figure 3**
Sound rays for flat terrain in case of downward refraction.
In the propagation model the actual position of the ray path (height of the ray along the path) determined as described in Sections 5.5.2 through 5.5.5 is not used directly. Only the calculated ray variables described in Section 5.5.1 are used. However, in a few cases (efficiency of scattering zones and reflecting surfaces) the height of the ray is important. In these cases the ray path is determined using another principle as described in Section 5.5.7.
5.5.1 Ray Variables

The calculation of the effect of sound propagation in the sub-models described in Sections 5.10 through 5.15 is based on a number of propagation variables. The propagation variables depend on whether the sound ray is a direct ray from source to receiver or a ray reflected by the ground.

The variables for the direct ray are:

- The travel time $\tau$ along the sound ray from source $S$ to receiver $R$
- The travel distance $R$ along the sound ray from source $S$ to receiver $R$
- The change in vertical ray angle $\Delta \theta$ at source and receiver relative to straight line propagation
- Distance $d_{SZ}$ from the source to a possible shadow zone (in upward refraction only)

The variables for the reflected ray are (only relevant if the receiver is not in a shadow zone):

- The travel time $\tau$ along the sound ray from source $S$ to receiver $R$
- The travel distance $R$ along the sound ray from source $S$ to receiver $R$
- The change in vertical ray angles $\Delta \theta_S$ and $\Delta \theta_R$ at source and receiver relative to straight line propagation
- Ground reflection angle $\psi_G$ (grazing angle) for a ray reflected by the ground

The calculation of propagation variables which is described in Section 5.5 is based on the assumption that ray paths are circular. The vertical log-lin sound speed defined in Section 5.3.2 will not produce circular rays. The first step will therefore be to determine the equivalent linear sound speed profile as shown in Section 5.5.2.

5.5.2 Equivalent Linear Sound Speed Profile

If the sound speed profile is a linear function of the height above ground the propagation the sound rays are circular rays and the propagation variables can be calculated using simple equations for such rays.

The equivalent linear sound speed profile has been introduced to use the simple and fast equations of circular rays. The equivalent linear sound speed profile is the profile leading approximately the same calculated propagation effect as more advanced methods which can take into account non-linear sound speed profiles.

For flat terrain the equivalent sound speed profile depends on the sound speed profile coefficients $A$, $B$, $C$, and $z_0$ and on the source and receiver heights $h_S$ and $h_R$. 
The equivalent linear sound speed profile is defined by Eq. (15) where $z$ is the height above ground, $c_0$ is the sound speed at the height 0 and $\Delta c/\Delta z$ is vertical sound speed gradient.

$$c_z(z) = c_0 + \frac{\Delta c}{\Delta z} z$$  \hspace{1cm} (15)

When used in the calculations, Eq. (15) is rewritten as shown in Eq. (16) where $\xi$ is the relative sound speed gradient defined by Eq. (17).

$$c_z(z) = c_0 \left(1 + \xi z\right)$$  \hspace{1cm} (16)

$$\xi = \frac{\Delta c/\Delta z}{c_0}$$  \hspace{1cm} (17)

$\Delta c/\Delta z$ is determined as the average gradient between the source and receiver heights $h_S$ and $h_R$ by Eq. (18) or if $h_S = h_R$ by the gradient at the height (in this case Eq. (18) can be applied by using the modified source height $h_S - 0.005$ m and the modified receiver height $h_R + 0.005$ m).

$$\frac{\Delta c}{\Delta z} = \frac{c(h_R) - c(h_S)}{h_R - h_S}$$  \hspace{1cm} (18)

The average sound speed $\bar{c}$ between the heights $h_S$ and $h_R$ is determined by Eq. (19). The integral in the equation is determined as shown in Annex F.

$$\bar{c} = \frac{1}{h_R - h_S} \int_{h_S}^{h_R} c(z) \, dz$$  \hspace{1cm} (19)

Finally $c_0$ is calculated by Eq. (20).

$$c_0 = \bar{c} - \frac{\Delta c}{\Delta z} \frac{h_S + h_R}{2}$$  \hspace{1cm} (20)

When using Eqs. (18) to (20) $h_S$ or $h_R$ shall not be less than $h_{\text{min}} = 5z_0$ where $z_0$ is the roughness length.

When $|\xi|$ becomes less than $10^{-6}$ then the values $\xi = 0$ and $\bar{c} = c_0 = C$ are used instead.

In the following the calculation procedure described above will be referred to by the function $\text{CalcEqSSP}$ defined in Eq. (21).

$$(\xi, c_0, \bar{c}) = \text{CalcEqSSP}(h_S, h_R, z_0, A, B, C)$$  \hspace{1cm} (21)
The same method is used in the propagation models containing screens but in this connection separate equivalent profiles are determined between source and the nearest screen, between receiver and the nearest screen and between screens if there are more than two screens. If the ray is starting or ending at a screen top the height of the source or receiver is replaced by an equivalent height denoted $h''_{SCR}$ which depend on the propagation distance. Therefore, in case of screens the equivalent sound speed profile will also depend on the propagation distance.

The height $h''_{SCR}$ is calculated by Eq. (22) on a basis of a modified propagation distance $R''_{SCR}$. $R_{ST}$ and $R_{RT}$ are the distances from source and receiver to the screen top $T$, respectively.

$$h''_{SCR} = \begin{cases} \frac{4R''_{SCR} - 75}{135} & R''_{SCR} > 75 \\ 0 & R''_{SCR} \leq 75 \end{cases}$$

(22)

where

$$R''_{SCR} = R_{SR} + \min(R_{ST}, R_{RT})$$

5.5.3 Modification of the Equivalent Linear Sound Speed Profile for Terrain Effect

For the terrain effect of a hard surface, the diffraction effect of a screen, and when calculating the size of a Fresnel-zone, the equivalent linear sound speed profile defined by $\xi$ and $c_0$ is independent of the one-third octave band frequency.

However, for the terrain effect of a soft surface (defined as a surface with a flow resistivity $\sigma$ less than 10,000,000 Pasm$^{-2}$) an equivalent linear sound speed profile is used that depends on the frequency $f$.

Above a frequency $f_H$ the variables $\xi$ and $c_0$ are determined by Eq. (21). Below a frequency $f_L$, $\Delta c/\Delta z$ is assumed to be zero and in the frequency range from $f_L$ to $f_H$ the modified sound speed gradient $\Delta c'/\Delta z$ given by Eq. (23) is used instead of $\Delta c/\Delta z$ when determining $\xi$ and $c_0$ according to Section 5.5.2.

$$\frac{\Delta c'}{\Delta z} = \frac{\log f - \log f_L}{\log f_H - \log f_L} \frac{\Delta c}{\Delta z}$$

(23)

The frequencies $f_L$ and $f_H$ are determined on basis of the frequency $f_\pi$ and $f_{2\pi}$ corresponding to phase differences $\pi$ and $2\pi$ calculated by Eqs. (24) and (25) where PhaseDiffFreq is the auxiliary function described in Section 5.23.14. $d$ is the horizontal propagation distance, $h_s$ is the source height, $h_R$ is the receiver height, $Z_c(f)$ is the terrain impedance (complex number) as a function of the one-third octave band frequency from 25 Hz to 10 kHz, and the $c_0$ is the sound speed at the ground. If $d$ is greater than 400 m the value 400 m is used...
instead and if \( h_S \) or \( h_R \) is less 0.5 m the value 0.5 m is used instead when applying Eqs. (24) and (25).

\[
f_\pi = \text{PhaseDiffFreq}(d, h_S, h_R, \hat{Z}_G(f), c_0, \pi)
\]

\[
f_{2\pi} = \text{PhaseDiffFreq}(d, h_S, h_R, \hat{Z}_G(f), c_0, 2\pi)
\]

The frequency \( f_L \) can now be calculated by Eq. (26) where \( \Delta c_{10} \) is the difference in sound speed 10 m above the ground and at the ground (\( \Delta c_{10} = c(10) - c(0) \)).

\[
f_L = \begin{cases} 
  f_\pi & \Delta c_{10} \leq 1 \\
  \frac{43 - 3\Delta c_{10}}{40} f_\pi & 1 < \Delta c_{10} < 5 \\
  0.7 f_\pi & \Delta c_{10} \geq 5 
\end{cases}
\]

Finally the frequency \( f_H \) can be calculated by Eq. (27).

\[
f_H = \max\left(\sqrt{\frac{f_L f_{2\pi}}{1.25 f_L}}, 1.25 f_L\right)
\]

In the following the calculation procedure described above will be referred to by the function \( \text{CalcEqSSP} \) defined in Eq. (28). The variables \( \xi(f) \) and \( c_0(f) \) are the frequency dependent values obtained by the procedure described in this section whereas the variables \( \xi \) and \( c_0 \) are the frequency independent values obtained by the function \( \text{CalcEqSSP} \) defined in Eq. (21).

\[
(\xi(f), c_0(f), c_r, \xi, c_0) = \text{CalcEqSSP}(h_S, h_R, \hat{Z}_G(f), z_0, A, B, C)
\]

5.5.4 Calculation of Ray Variables for a Direct Ray

As mentioned in Section 5.5.1 the variables used for the direct ray between source and receiver (or screen tops) when predicting the propagation effect are:

- The travel time \( \tau \) along the sound ray
- The travel distance \( R \) along the sound ray
- The change in vertical ray angle \( \Delta \theta \) at the beginning or end of the sound ray relative to straight line propagation
- Distance \( d_{SZ} \) from the source, receiver or screen top to a possible shadow zone (in upward refraction only)
In Figure 7 the variables $\tau$, $R$, and $\Delta \theta$ are defined together with other variables used when calculating the ray variables. In the calculation it is assumed that the sound is propagating along a circular ray from the ray point L to ray point U. L and U can be source, receiver or a screen top and L and U are the lower and upper position, respectively.

**Figure 7**
Definition of geometrical parameters for a direct ray.

In order to calculate the ray variables Eq. (16) and (17) have to be redefined as shown in Eq. (29) to (31) unless the point L is at the ground. $z'$ is the height above the point L ($z' = z - z_L$).

\[
 c_0'(z') = c_0' \left(1 + \xi' z' \right) \quad \text{(29)}
\]

\[
 \xi' = \frac{\Delta c/\Delta z}{c_0'} = \frac{\xi}{1 + \xi z_L} \quad \text{(30)}
\]

\[
 c_0' = c_0 \left(1 + \xi z_L \right) \quad \text{(31)}
\]

The first step is to calculate the angle $\psi_L$ and horizontal distance $d_m$ from L to the top point of the circle as shown in Figure 7. $\psi_L$ and $d_m$ are calculated by Eqs. (32) and (33) where $\Delta z$ is defined as the height of U above L ($\Delta z = z_U - z_L$) and $d$ is the horizontal distance between L and U.

\[
 \tan \psi_L = \frac{\xi' d}{2} + \frac{\Delta z \left(2 + \xi' \Delta z\right)}{2d} \quad \text{(32)}
\]

\[
 d_m = \frac{\tan \psi_L}{\xi'} \quad \text{(33)}
\]

If $\xi > 0$ and $d \leq d_m$, $R$ and $\tau$ are calculated by Eqs. (34) through (37).
\begin{equation}
R(\Delta z) = \frac{1}{\xi'} \cos (\psi_L) \left( \arcsin \left( (1 + \xi' \Delta z) \cos (\psi_L) \right) - \frac{\pi}{2} + \psi_L \right) \tag{34}
\end{equation}

\begin{equation}
\tau (\Delta z) = \frac{1}{2 \xi' \epsilon_0} \ln \left( \frac{f(0)}{f(\Delta z)} \right) \tag{35}
\end{equation}

where

\begin{equation}
f(0) = \frac{1 + \sin \psi_L}{1 - \sin \psi_L} \tag{36}
\end{equation}

and

\begin{equation}
f(\Delta z) = \frac{1 + \sqrt{1 - (1 + \xi' \Delta z)^2 \cos^2 \psi_L}}{1 - \sqrt{1 - (1 + \xi' \Delta z)^2 \cos^2 \psi_L}} \tag{37}
\end{equation}

If \( d > d_m \), \( R \) and \( \tau \) are instead calculated by Eqs. (38) to (40) where \( \Delta z_m \) is the height of the ray at the top point of the circle at the horizontal distance \( d_m \). \( R(\Delta z_m) \) and \( R(\Delta z) \) are calculated by Eq. (34) and \( \tau(\Delta z_m) \) and \( \tau(\Delta z) \) by Eq. (35).

\begin{equation}
\Delta z_m = \frac{1}{\xi'} \left( \frac{1}{\cos (\psi_L)} - 1 \right) \tag{38}
\end{equation}

\begin{equation}
R = 2 R(\Delta z_m) - R(\Delta z) \tag{39}
\end{equation}

\begin{equation}
\tau = 2 \tau(\Delta z_m) - \tau(\Delta z) \tag{40}
\end{equation}

Finally the change in ray angle \( \Delta \theta \) compared to a straight line ray between \( L \) and \( U \) can be determined by Eq. (41).

\begin{equation}
\Delta \theta = \psi_L - \arctan \left( \frac{\Delta z}{d} \right) \tag{41}
\end{equation}

If \( \xi' \) is less than zero \( R, \tau \) and \( \Delta \theta \) are also determined by Eqs. (32) through (41) using the absolute value of \( \xi' \) (\( \xi' = |\xi'| \)) but in this case the calculated value of \( \Delta \theta \) has to be multiplied by \(-1\) as shown in Eq. (42).

\begin{equation}
\Delta \theta(\xi < 0) = - \Delta \theta(\xi > 0) \tag{42}
\end{equation}
The equations shown above will when $\Delta z$ is approaching 0 give rise to numerical problems when being implemented in computer code. Therefore, when $\Delta z$ becomes less than 0.01 a value of 0.01 should be used instead. Furthermore, the equations cannot be used when $\xi$ becomes 0 (homogeneous atmosphere). Therefore, when $|\xi| < 10^{-10}$, $\xi = 10^{-10}$ has to be used instead.

If $\xi$ is less than zero a part of the ray may be below the ground indicating a shadow zone. The propagation distance $d_{SZ}$ where the ray is just grazing the ground for a given value of $\xi$ is the distance above which shadow zone propagation will occur. $d_{SZ}$ is calculated by Eq. (43).

$$d_{SZ} = \sqrt{z_L \left( \frac{2}{|\xi|} - z_L \right)} + \sqrt{z_U \left( \frac{2}{|\xi|} - z_U \right)}$$

(43)

To avoid numerical problems in the calculations, shadow propagation shall be assumed when the horizontal propagation distance $d$ is greater than $0.95 d_{SZ}$.

The calculation procedure described above will in the following be referred to by the function $DirectRay$ defined in Eq. (44). If $\xi \geq 0$, the variable $d_{SZ}$ is fixed at infinity ($\infty$).

$$(\tau, R, \Delta \theta, \xi, d_{SZ}) = DirectRay(d, h_s, h_r, \xi, \xi_0)$$

(44)

### 5.5.5 Calculation of Ray Variables for a Ray Reflected by the Ground

If $\xi$ is less than zero and the horizontal propagation distance $d$ is greater than $0.95 d_{SZ}$ where $d_{SZ}$ has been calculated in the previous section (shadow zone propagation) the ray variables of the reflected ray shall not be determined.

Otherwise, as mentioned in Section 5.5.1 the variables used for the reflected ray between “source” and “receiver” (the beginning and end of the ray may also be a screen edge) when predicting the propagation effect are:

- The travel time $\tau$ along the sound ray
- The travel distance $R$ along the sound ray
- The travel distance $R_S$ along the sound ray from source to reflection point
- The travel distance $R_R$ along the sound ray from receiver to reflection point
- The change in vertical ray angles $\Delta \theta_S$ and $\Delta \theta_R$ of the sound ray at the “source”or the “receiver” relative to straight line propagation
- Ground reflection angle $\psi_G$ (grazing angle) for a ray
In Figure 8 the variables $\tau = \tau_s + \tau_r$, $R = R_s + R_r$, $\Delta \theta_s$, $\Delta \theta_r$, and $\psi_G$ are defined together with other variables used when calculating the ray variables.

**Figure 8**
*Definition of geometrical parameters for a reflected ray.*

For the reflected ray the ray variables are calculated by the equations shown in Section 5.5.4 but the calculation is done separately for part of the ray from the reflection point P to the “source” S and for part of the ray from the reflection point P to the “receiver” R as shown in Eq. (45) and (46). $d_s$ and $d_r$ are the distances from the reflection point to the “source” or “receiver” and NA indicates that the distance $d_{SZ}$ will not be applied (the calculation for reflected ray will not be carried out in case of shadow zone propagation). Also the change in ray angle $\Delta \theta$ cannot be applied as the position of the reflection point P is not the same in the straight line propagation case.

\[
\begin{align*}
(\tau_s, R_s, NA, NA, NA) &= DirectRay(d_s, 0, h_s, \xi, c_0) \\
(\tau_r, R_r, NA, NA, NA) &= DirectRay(d_r, 0, h_r, \xi, c_0)
\end{align*}
\]

(45)  

(46)

The grazing reflection angle $\psi_G$ is equal to $\psi_L$ calculated when applying the function $DirectRay$ ($\psi_L$ will be the same for the “source” and “receiver” part of the ray) and the change in the ray angles $\Delta \theta_s$ and $\Delta \theta_r$ can be determined by Eqs. (47) and (48).

\[
\begin{align*}
\Delta \theta_s &= \psi_G + \arctan \frac{z_s + z_r}{d} - 2 \arctan \frac{z_s}{d_S} \\
\Delta \theta_r &= \psi_G + \arctan \frac{z_s + z_r}{d} - 2 \arctan \frac{z_r}{d_R}
\end{align*}
\]

(47)  

(48)

However, before calculating the ray variables the position of the reflection point P has to be determined.
In downward refraction ($\xi > 0$) the reflection point is determined by finding the roots $d_{\text{refl}}$ of the cubic equation in Eq. (49). A method for determining the roots of cubic equation can be found in [5].

$$2d_{\text{refl}}^3 - 3dd_{\text{refl}}^2 + (b_R^2 + b_S^2 + d^2)d_{\text{refl}} - b_S^2d = 0$$

where

$$b_S^2 = \frac{z_S}{\xi} (2 + \xi z_S)$$

and

$$b_R^2 = \frac{z_R}{\xi} (2 + \xi z_R)$$

Eq. (49) may have up to three real roots for large values of $\xi$. If the equation has more than one real solution the reflection point closest to the source is used when the source height $h_S$ is less than the receiver height while the reflection point closest to the receiver is used when the source height is greater than the receiver height.

In upward refraction ($\xi > 0$) the reflection point is also determined by Eq. (49) but in this case there will be only one real solution.

The calculation procedure described above will in the following be referred to by the function $\text{Reflected}$ defined in Eq. (50).

$$\left(\tau, R, R_S, R_R, \Delta \theta_S, \Delta \theta_R, \psi_G, d_{\text{refl}}\right) = \text{Reflected}(d, h_S, h_R, \xi, c_0)$$

5.5.6 Difference in Travel Time between the Direct and Reflected Ray

In the Nord2000 sub-models described in the following section one of the most important variables is the difference in travel time $\Delta \tau$ between the travel time $\tau_2$ along the reflected ray and the travel time $\tau_1$ along the direct ray as defined in Eq. (51).

$$\Delta \tau = \tau_2 - \tau_1$$

The travel time difference $\Delta \tau$ determines the phase difference between the direct and reflected sound which is essential to sound interference effects. Therefore, it is very important that $\Delta \tau$ is calculated with the highest possible accuracy. As $\Delta \tau$ normally is the difference between two numbers almost equal ($\tau_2 \approx \tau_1 \gg \Delta \tau$) it is recommended to use variables with the highest possible precision for $\tau_2 \approx \tau_1$ when implementing the method into computer code.
For very high sources (or receivers) the calculation of the travel time difference $\Delta \tau$ described above has been found to fail in upward refraction at the edge of a meteorological shadow zone where $\Delta \tau$ has to be zero.

To solve this problem when $\xi < 0$, a maximum travel time difference $\Delta \tau_0$ is calculated by Eq. (52) where $C$ is the sound speed at the ground.

$$\Delta \tau_0 = \left( 1 - \left( \frac{d}{d_{SZ}} \right)^2 \right) \frac{\sqrt{d^2 + (h_S + h_R)^2} - \sqrt{d^2 + (h_S - h_R)^2}}{C}$$  \hspace{1cm} (52)

If $\Delta \tau$ is greater than $\Delta \tau_0$ the latter is used instead. This ensures that $\Delta \tau$ will be zero at the edge of the shadow zone.

The calculation procedure described above will in the following be referred to by the function $\text{TravelTimeDiff}$ defined in Eq. (53).

$$\Delta \tau = \text{TravelTimeDiff}(\tau_1, \tau_2)$$  \hspace{1cm} (53)

If the receiver is in a shadow zone ($d > 0.95 \ d_{SZ}$ where $d_{SZ}$ is calculated by the function $\text{DirectRay}$) $\Delta \tau$ is fixed at a value of zero.

### 5.5.7 Calculation of the Height of a Ray

As mentioned in the introduction of Section 5.5 the exact ray path is in most cases not used directly but only for determining the ray variables. However, in a few cases (efficiency of scattering zones and reflecting surfaces) the height of the ray becomes important. In these cases the ray path is determined using another principle as described in this section.

Eq. (54) shows how the ray curvature is determined in case of a log-lin sound speed profile as defined in Eq. (2) by the weather coefficients $A$, $B$, and $C$. The radius of curvature $R_{A,B}$ is determined on basis of radii $R_A$ and $R_B$ of the logarithmic and linear part of the sound speed profile, respectively. $d$ is the horizontal distance.

$$R_A = \text{sign}(A) \frac{d}{8} \sqrt{\frac{2\pi C}{|A|}}$$

$$R_B = \text{sign}(B) \left( \frac{C}{|B|} \right)^2 + \left( \frac{d}{2} \right)^2$$

$$R_{A,B} = \frac{1}{1 + \frac{1}{R_A} + \frac{1}{R_B}}$$  \hspace{1cm} (54)
The relative sound speed gradient \( \xi_{ray} \) of the equivalent sound speed profile corresponding to \( R_{A,B} \) is determined by Eq. (55) where \( \psi_S \) is the start angle of the ray at the source. \( h_S \) and \( h_R \) is the source and receiver height.

\[
\xi_{ray} = \frac{1}{R_{A,B} \cos(\psi_S)}
\]

\[
\psi_S = \arcsin \left( \frac{\sqrt{d^2 + (h_R - h_S)^2}}{2R_{A,B}} \right) + \arctan \left( \frac{h_R - h_S}{d} \right)
\]

(55)

The procedure described in this section for calculating position of the circular ray path defined by the radius of curvature \( R_{A,B} \) and the corresponding relative sound speed gradient \( \xi_{ray} \) is referred to by the function \( RayCurvature \) defined in Eq. (56).

\[
\left( R_{A,B}, \xi_{ray} \right) = RayCurvature(A, B, C, d, h_S, h_R)
\]

(56)

5.6 Terrain Surface Properties

As mentioned in Section 5.3.1 the surface properties of each segment in the terrain profile is defined by the flow resistivity \( \sigma \) and ground roughness \( r \). In the Nord2000 method the flow resistivity used is the effective flow resistivity giving the best fit between calculated impedance applying Delany and Bazley impedance model and the actual impedance of the surface. The effective flow resistivity can be measured according to a Nordtest method [6]. The ground roughness parameter \( r \) is a variable that quantify the unevenness of the terrain segment if not perfectly flat. The ground roughness is the standard deviation of the random height variations within the segment.

In the following sections the method for calculating the ground impedance on basis of the flow resistivity will be described and a number of reflection coefficients used in Nord2000 will be defined.

The ground roughness will affect the coherence coefficient \( F_r \) of the model which is described in Section 0.

5.6.1 Classification of Surface Properties

The method can be used for any value of the flow resistivity \( \sigma \) and ground roughness \( r \). However, for practical use a classification has been made which include a number of ground surface types representing typical surfaces.

The classification of flow resistivity which is based on the Nordtest flow resistivity classes [6] is shown in Table 2.
<table>

### 5.6.2 Ground Impedance

The ground impedance $Z_G$ as a function of the frequency is calculated by the Delany and Bazley model as shown in Eq. (57) where $\sigma$ is the flow resistivity and $f$ is the one-third octave band centre frequency.
\[
\hat{Z}_G(f) = 1 + 9.08 \left( \frac{1000 f}{\sigma} \right)^{-0.75} + j 11.9 \left( \frac{1000 f}{\sigma} \right)^{-0.73}
\] (57)

5.6.3 Spherical-Wave Reflection Coefficient

The spherical wave reflection coefficient \( Q \) is a function of the frequency \( f \), the travel time \( \tau_2 \) along the reflected ray, the grazing reflection angle \( \psi_G \), and the ground impedance \( Z_G \). \( Q \) is calculated by Eq. (58) where \( \hat{R}_p(f, \psi_G) \) is the plane wave reflection coefficient calculated by Eq. (59) and the function \( \hat{E}(\hat{\rho}) \) is calculated by Eq. (60).

\[
\hat{Q}(f, \tau_2, \psi_G, \hat{Z}_G) = \hat{R}_p(f, \psi_G) + (1 - \hat{R}_p(f, \psi_G))\hat{E}(\hat{\rho})
\] (58)

\[
\hat{R}_p(f, \psi_G) = \frac{\sin(\psi_G) - \frac{1}{Z_G(f)}}{\sin(\psi_G) + \frac{1}{Z_G(f)}}
\] (59)

\[
\hat{E}(\hat{\rho}) = 1 + j\sqrt{\pi} \hat{\rho} e^{-\hat{\rho}^2} \text{erfc} (-j\hat{\rho})
\]

where

\[
\hat{\rho} = \frac{1 + j}{2} \sqrt{\omega \tau_2} \left( \frac{\sin(\psi_G) + \frac{1}{Z_G}}{Z_G} \right)
\] (60)

The complex function \( w(\hat{\rho}) = e^{-\hat{\rho}^2} \text{erfc} (-j\hat{\rho}) \) in Eq. (60) where \( \text{erfc} \) is the complementary error function extended to complex arguments can be determined by an approximate method as described in the following Eqs. (61) through (74). \( x \) and \( y \) are the real and imaginary parts of \( \hat{\rho} = x + jy \). * denotes complex conjugation and \( w_* \) is calculated by Eq. (61) or (62).

The procedure when \( |x| > 3.9 \lor |y| > 3 \) is given by Eqs. (61) through (64):

\[
\hat{\rho}_* = |x| + j|y|
\] (61)

\[
w(\hat{\rho}) = \begin{cases} 
  w_*(\hat{\rho}_*) & x < 0 \land y > 0 \\
  w_*(\hat{\rho}_*) & x > 0 \land y > 0 \\
  2e^{-|\rho_*|^2} - w_*(\hat{\rho}_*) & y < 0 
\end{cases}
\] (62)

\( x > 6 \lor y > 6 \):
\[ w_\varepsilon(\hat{\rho}) = j\hat{\rho} \left( \frac{0.5124242}{\hat{\rho}^2 - 0.2752551} + \frac{0.05176536}{\hat{\rho}^2 - 2.724745} \right) \]  

\text{else} 

\[ w_\varepsilon(\hat{\rho}) = j\hat{\rho} \left( \frac{0.4613135}{\hat{\rho}^2 - 0.1901635} + \frac{0.09999216}{\hat{\rho}^2 - 1.7844927} + \frac{0.002883894}{\hat{\rho}^2 - 5.5253437} \right) \]  

The procedure when \(|x| \leq 3.9 \wedge |y| \leq 3\) is given by Eqs. (65) through (74):

\[ h = 0.8 \]  

\[ A_i = \cos(2 x y) \]  

\[ B_i = \sin(2 x y) \]  

\[ C_1 = e^{-2\pi x/h} - \cos \left( 2 x \pi / h \right) \]  

\[ D_1 = \sin \left( 2 x \pi / h \right) \]  

\[ P_2 = 2e^{-\left(x^2 + 2y^2 + h^2\right)} \frac{A_1 C_1 - B_1 D_1}{C_1^2 + D_1^2} \]  

\[ Q_2 = 2e^{-\left(x^2 + 2y^2 + h^2\right)} \frac{A_1 D_1 + B_1 C_1}{C_1^2 + D_1^2} \]  

\[ H = \frac{h y}{\pi(x^2 + y^2)} + \frac{2 y h}{\pi} \sum_{n=1}^{5} \frac{e^{-n^2 h^2} \left(x^2 + y^2 + n^2 h^2\right)}{\left(y^2 - x^2 + n^2 h^2\right)^2 + 4x^2 y^2} \]  

\[ K = \frac{h x}{\pi(x^2 + y^2)} + \frac{2 x h}{\pi} \sum_{n=1}^{5} \frac{e^{-n^2 h^2} \left(x^2 + y^2 - n^2 h^2\right)}{\left(y^2 - x^2 + n^2 h^2\right)^2 + 4x^2 y^2} \]  

\[ w(\hat{\rho}) = H + P_2 + j \left(K - Q_2\right) \]  

### 5.6.4 Incoherent Reflection Coefficient

The incoherent reflection coefficient \(9\varepsilon\) which is a function of the frequency and the ground impedance \(Z_G\) is based on the random incidence absorption coefficient \(\alpha_{ri}\) and is defined by Eq. (75).
\[ \Re_i(f, \hat{Z}_G) = \sqrt{1 - \alpha_n(f, \hat{Z}_G)} \quad (75) \]

\(\alpha_n\) is calculated by Eq. (76) where \(X\) and \(Y\) is the real and imaginary part of the ground impedance \(\hat{Z}_G\).

\[ \alpha_n(f, \hat{Z}_G) = 8 \frac{X}{X^2 + Y^2} \left\{ 1 - \frac{X}{X^2 + Y^2} \ln \left( (1 + X)^2 + Y^2 \right) \right\} \]

\[ + \frac{X^2 - Y^2}{(X^2 + Y^2) Y} \arctan \left( \frac{Y}{1 + X} \right) \quad (76) \]

where

\[ \hat{Z}_G(f) = X + jY \]

The advantage of using an incoherent reflection coefficient for the incoherent part of the sound field is that the calculation of \(\Re_i\) is faster than the calculation of spherical-wave reflection coefficient \(Q\) and because \(\Re_i\) is not a function of the ground reflection angle as \(Q\) is, it is possible to pre-calculate \(\Re_i\) for each impedance type in the prediction model. At high frequencies where the ray contributions become fully incoherent in most cases (coherence coefficient \(F = 0\)) the calculation time can be reduced considerably as the calculation of the ground reflection coefficient can be replaced by a table look-up.

5.6.5 Plane-Wave Reflection Coefficient

The plane-wave reflection coefficient \(\hat{R}_p\) is a function of the frequency, the grazing reflection \(\psi_G\) and ground impedance \(\hat{Z}_G\) and is calculated by Eq. (77). The plane-wave reflection coefficient is used in the multiple ground reflection model.

\[ \hat{R}_p(f, \psi_G, \hat{Z}_G) = \frac{\sin(\psi_G) - \frac{1}{\hat{Z}_G(f)}}{\sin(\psi_G) + \frac{1}{\hat{Z}_G(f)}} \quad (77) \]

5.7 Propagation Effect of a Wedge-Shaped Screen

This section contains procedures used when calculating the propagation effects of a wedge-shaped screen in the sub-models described in Sections 5.13 to 5.15.
5.7.1 Diffraction of a Wedge with Finite Surface Impedance

This section describes the procedure used in the Nord2000 method to calculate the sound pressure at the receiver when sound propagates from a point source over a finite impedance wedge.

The input variables in the model are:

- The travel time $\tau_S$ from source S to the top of the wedge T
- The travel time $\tau_R$ from T to receiver R
- The travel time $\tau$ from S to R over T (normally $\tau = \tau_S + \tau_R$ but when used in the procedure for a two-edge screen $\tau$ may be defined otherwise)
- The travel distance $R_S$ from S to T
- The travel distance $R_R$ from T to R
- The travel distance $\ell$ from S to R over T (normally $\ell = R_S + R_R$ but when used in the procedure for a two-edge screen $R$ may be defined otherwise)
- The source diffraction angle $\theta_S$ re. receiver wedge face
- The receiver diffraction angle $\theta_R$ re. receiver wedge face
- Wedge angle $\beta$
- Surface impedance $Z_S$ of source wedge face
- Surface impedance $Z_R$ of receiver wedge face

In the presentation of the solution shown in the following it is assumed that $0 \leq \theta_S \leq \beta \leq 2\pi$. If this is not the case the angles have to be modified as described in the end of the section.

The input variables are illustrated in Figure 9 for a non-refracting atmosphere. For a refracting atmosphere the refraction-modified geometrical parameters used in the diffraction solution the rays S-T and R-T will be arcs instead.
Figure 9

Definition of variables used when calculating of the sound pressure level behind a wedge-shaped screen with finite surface impedances.

The sound pressure level at the receiver \( p_{\text{diff}} \) is calculated by Eq. (78) where \( \omega \) is the angular frequency (=2\( \pi \)f)

\[
\hat{p}_{\text{diff}}(f) = -\frac{1}{\pi} \sum_{n=1}^{4} \hat{Q}_n A(\theta_n) \hat{E}_v(A(\theta_n)) e^{j\omega \tau} \tag{78}
\]

The angle \( \theta_n \) in Eq. (78) is defined by Eq. (79).

\[
\begin{align*}
\theta_1 &= \theta_s - \theta_R \\
\theta_2 &= \theta_s + \theta_R \\
\theta_3 &= 2\beta - (\theta_s + \theta_R) \\
\theta_4 &= 2\beta - (\theta_s - \theta_R)
\end{align*} \tag{79}
\]

The "reflection coefficient" \( Q_n \) in Eq. (78) is calculated by Eq. (80).

\[
\begin{align*}
Q_1 &= 1 \\
Q_2 &= Q_S \left( f, \tau_s + \tau_R, \min(\beta - \theta_s, \pi/2), \hat{Z}_S \right) \\
Q_3 &= Q_R \left( f, \tau_s + \tau_R, \min(\theta_R, \pi/2), \hat{Z}_R \right) \\
Q_4 &= Q_S \left( f, \tau_s + \tau_R, \min(\beta - \theta_s, \pi/2), \hat{Z}_S \right) Q_R \left( f, \tau_s + \tau_R, \min(\theta_R, \pi/2), \hat{Z}_R \right)
\end{align*} \tag{80}
\]

The function \( \hat{E}_v(A(\theta_n)) \) is calculated by Eq. (81) where \( v = \pi/\beta \) is the wedge index. The solution is only valid for \( \beta > \pi \).
\[
\hat{E}_n(A(\theta_n)) = \frac{\pi}{\sqrt{2}} \frac{\sin[A(\theta_n)]}{|A(\theta_n)|} \frac{e^{j\pi/4}}{\sqrt{1 + \left(\frac{2\tau_s \tau_R}{\tau^2} + \frac{1}{2}\right)\cos^2[A(\theta_n)]}} \hat{A}_D(B)
\] (81)

In Eq. (81) \(A(\theta_n)\) is given by Eq. (82), \(B\) by Eq. (83) and \(A_D(B)\) by Eq. (84). In Eq. (82) \(H(x)\) is Heavisides' step function calculated by the auxiliary function \(H\) and in Eq. (84) \(\text{Sign}(x)\) is the Signum function calculated by the auxiliary function \(\text{Sign}\).

\[
A(\theta_n) = \frac{\nu}{2}(\beta - \pi + \theta_n) + \pi H(\pi - \theta_n)
\] (82)

\[
B = \sqrt{\frac{4\pi \tau_s \tau_R}{\nu \pi}} \frac{\cos[A(\theta_n)]}{\sqrt{\nu^2 + \left(\frac{2\tau_s \tau_R}{\tau^2} + \frac{1}{2}\right)\cos^2[A(\theta_n)]}}
\] (83)

\[
\hat{A}_D(B) = \text{Sign}(B)\left(f(|B|) - jg(|B|)\right)
\] (84)

In Eq. (84) the functions \(f(x)\) and \(g(x)\) are the auxiliary Fresnel-functions calculated as shown in Eqs. (85) and (86). If \(x < 5\) \(f(x)\) and \(g(x)\) is calculated by a polynomial fit. The constants \(a_0\) to \(a_{12}\) are defined in Table 4 and Table 5 for \(f(x)\) and \(g(x)\), respectively.

\[
f(x) = \begin{cases} 
\frac{1}{\pi x} & x \geq 5 \\
\sum_{n=0}^{12} a_n x^n & x < 5 
\end{cases}
\] (85)

\[
g(x) = \begin{cases} 
\frac{1}{\pi^2 x^3} & x \geq 5 \\
\sum_{n=0}^{12} a_n x^n & x < 5 
\end{cases}
\] (86)

  a_0 &= 0.50002414586702
\end{align*}

**Table 5**

*Constants in polynomial fit of \( g(x) \) for \( x < 5 \).*

If \( \theta_n = \pi \) numerical problems will occur when calculating the diffracted sound pressure by Eq. (78). This can be fixed by subtracting a small quantity \( \varepsilon \) from \( \theta_n \) when \( |\theta_n - \pi| < \varepsilon \). \( \varepsilon = 10^{-8} \) has been found suitable but may depend on the implementation in program code.
If \( \theta_1 > \pi \) (wedge edge is above the line from the source to the receiver) the sound pressure at the receiver is determined by \( \hat{p}_{\text{diff}} \) as shown in Eq. (87).

\[
\hat{p} = \hat{p}_{\text{diff}}
\]  

(87)

If \( \theta_1 < \pi \) (wedge edge is below the line from the source to the receiver) the contribution from the direct ray shall be added to the solution as shown in Eq. (88).

\[
\hat{p} = \hat{p}_{\text{diff}} + \frac{e^{j\omega t}}{R_1}
\]

where

\[
R_1 = \sqrt{R_s^2 + R_R^2 - 2R_s R_R \cos(\theta_1)}
\]

\[
\tau_1 = \sqrt{\tau_s^2 + \tau_R^2 - 2\tau_s \tau_R \cos(\theta_1)}
\]

If \( \theta_2 < \pi \) (wedge edge is below the line from the source to the image receiver) the contributions from the direct ray as well as the ray reflected in the source face of the wedge shall be added to the solution as shown in Eq. (89). \( R_1 \) and \( \tau_1 \) are defined in Eq. (88). \( Q_R \) is the spherical-wave reflection coefficient calculated as shown in 5.6.3.

\[
\hat{p}(f) = \hat{p}_{\text{diff}}(f) + \frac{e^{j\omega t}}{R_1} + \hat{Q}_R(f, \tau_2, \psi_{G,R}, \hat{\tau}_R) \frac{e^{j\omega t}}{R_2}
\]

where

\[
R_2 = \sqrt{R_s^2 + R_R^2 - 2R_s R_R \cos(\theta_2)}
\]

\[
\tau_2 = \sqrt{\tau_s^2 + \tau_R^2 - 2\tau_s \tau_R \cos(\theta_2)}
\]

\[
\psi_{G,R} = \arcsin\left(\frac{R_s \sin \theta_s + R_R \sin \theta_R}{R_2}\right)
\]

If \( \theta_2 < \pi \) (wedge edge is below the line from the source to the image receiver) the contributions from the direct ray as well as the ray reflected in the receiver face of the wedge shall be added to the solution as shown in Eq. (90). \( R_1 \) and \( \tau_1 \) are defined in Eq. (88). \( Q_S \) is the spherical-wave reflection coefficient calculated as shown in 5.6.3.
\[ \hat{p}(f) = \hat{p}_{diff}(f) + \frac{e^{j\omega \gamma}}{R_1} + \hat{Q}_S(f, \tau_3, \psi_{G,S}, \hat{Z}_S) \frac{e^{j\omega \gamma}}{R_3} \]

where

\[ R_3 = \sqrt{R_s^2 + R_R^2 - 2R_s R_R \cos(\theta_3)} \]

\[ \tau_3 = \sqrt{\tau_s^2 + \tau_R^2 - 2\tau_s \tau_R \cos(\theta_3)} \]

\[ \psi_{G,S} = \arcsin \left( \frac{R_s \sin(\beta - \theta_s) + R_R \sin(\beta - \theta_R)}{R_3} \right) \]

In cases where the source and receiver are reflected by a ground surface before and after the wedge the calculation will also be carried out for the image source and receiver as described in Sections 5.13 to 5.15. In such cases the "source" or "receiver" may be inside the wedge. The same may happen when for the source and receiver in case of upward refraction. This is in both cases taken care of by modifying the angles according to the following scheme where \( \theta_R, \theta_S \) and \( \beta \) are the modified angles.

0 > \( \theta_R > \beta - 2\pi \):

\[ \theta_R = 0 \]

\[ \theta_S = \theta_S - \theta_R \]

\[ \beta' = \beta - \theta_R \]

\( \theta_R \leq \beta - 2\pi \):

\[ \theta_R = 0 \]

\[ \theta_S = 2\pi - (\beta - \theta_S) \]

\[ \beta' = 2\pi \]

\( \beta < \theta_S < 2\pi \) (\( \theta_S \) and \( \beta' \) are used instead of \( \theta_S \) and \( \beta \) when modified above):

\[ \beta' = \theta_S \]

\( \theta_S \geq 2\pi \) (\( \theta_S \) is used instead \( \theta_S \) when modified above):

\[ \theta_S = 2\pi \]

\[ \beta' = 2\pi \]
The procedure described above in this section will be referred to by the function \( \text{pwedge} \) as defined in Eq. (91).

\[
\hat{p}(f) = \text{pwedge}\left(f, \beta, \theta_S, \theta_R, \tau, \tau_S, \ell, R_R, R_R, \hat{Z}_S, \hat{Z}_R\right) \quad (91)
\]

5.7.2 Diffraction Coefficient

The diffraction coefficient \( \hat{D} \) is defined by Eq. (92). \( \hat{p} \) is calculated as described in Section 5.7.1 where \( \tau \) and \( \ell \) are defined.

\[
\hat{p}(f) = \hat{D}(f) e^{j\omega \tau} \quad (92)
\]

Therefore, the diffraction coefficient can be calculated by Eq. (93).

\[
\hat{D}(f) = \frac{\ell}{e^{j\omega \tau}} \text{pwedge}\left(f, \beta, \theta_S, \theta_R, \tau, \tau_S, \ell, R_R, R_R, \hat{Z}_S, \hat{Z}_R\right) \quad (93)
\]

The procedure described this section will be referred to by the function \( \text{Dwedge} \) as defined in Eq. (94).

\[
\hat{D}(f) = \text{Dwedge}\left(f, \beta, \theta_S, \theta_R, \tau, \tau_S, \ell, R_R, R_R, \hat{Z}_S, \hat{Z}_R\right) \quad (94)
\]

5.7.3 Diffraction of Two Wedge-Shaped Screens

This section describes the procedure used in the Nord2000 method to calculate the sound pressure at the receiver when sound propagates from a point source over two finite impedance wedges as shown in Figure 10. The wedge closest to the source is designated the first wedge (top edge \( T_1 \)) and the wedge closest to the receiver is designated the second wedge (top edge \( T_2 \)). In the following \( R_1, R_2 \) and \( R_3 \) in the figure are designated \( R_S, R_M, \) and \( R_R \).

\[\text{Figure 10}\]
\[\text{Propagation over two wedge-shaped screens.}\]
The input variables in the model are:

- The travel time $\tau_S$ from source $S$ to $T_1$
- The travel time $\tau_M$ from $T_1$ to $T_2$
- The travel time $\tau_R$ from receiver $R$ to $T_2$
- The travel distance $R_S$ from $S$ to $T_1$
- The travel distance $R_M$ from $T_1$ to $T_2$
- The travel distance $R_R$ from $R$ to $T_2$
- The source diffraction angle $\theta_{1S}$ of the first wedge
- The “receiver” diffraction angle $\theta_{1R}$ of the first wedge. If $T_2$ is above the line from $T_1$ to $R$, $\theta_{1R}$ is the angle between the receiver wedge face and the line $T_1T_2$. Otherwise $\theta_{1R}$ is the angle between the receiver wedge face and the line $T_1R$
- Wedge angle $\beta_1$ of the first wedge
- Surface impedance $Z_{1S}$ of source face of the first wedge
- Surface impedance $Z_{1R}$ of receiver face of first wedge
- The “source” diffraction angle $\theta_{2S}$ of the second wedge. If $T_1$ is above the line from $T_2$ to $S$, $\theta_{2S}$ is the angle between the receiver wedge face and the line $T_2T_1$. Otherwise $\theta_{2R}$ is the angle between the receiver wedge face and the line $T_2S$
- The receiver diffraction angle $\theta_{2R}$ of the second wedge
- Wedge angle $\beta_2$ of the second wedge
- Surface impedance $Z_{2S}$ of source face of the second wedge
- Surface impedance $Z_{2R}$ of receiver face of second wedge

The total travel time $\tau$ and distance $\ell$ is defined in by Eqs. (95) and (96).

$$\tau = \tau_S + \tau_M + \tau_R$$  \hspace{1cm} (95)

$$\ell = R_S + R_M + R_R$$  \hspace{1cm} (96)
If the first wedge is the most important wedge the sound pressure at the receiver \( \hat{p} \) is calculated by Eq. (97). The most important wedge in the terrain is determined in Section 5.21.

\[
\hat{p}(f) = \hat{D}_1(f)\hat{D}_2(f)\frac{e^{jk\ell}}{\ell}
\]

where

\[
\begin{align*}
\hat{D}_1(f) &= D_{wedge}\left(f, \beta_1, \theta_{1S}, \theta_{1R}, \tau, \tau_M + \tau_R, \ell, R_S, R_M + R_R, \hat{Z}_{1S}, \hat{Z}_{1R}\right) \\
\hat{D}_2(f) &= D_{wedge}\left(f, \beta_2, \theta_{2S}, \theta_{2R}, \tau_M + \tau_R, \tau_M, R_M + R_R, R_R, \hat{Z}_{2S}, \hat{Z}_{2R}\right)
\end{align*}
\]

If the second wedge is the most important wedge the sound pressure at the receiver \( \hat{p} \) is calculated by Eq. (98).

\[
\hat{p}(f) = \hat{D}_1(f)\hat{D}_2(f)\frac{e^{jk\ell}}{\ell}
\]

where

\[
\begin{align*}
\hat{D}_1(f) &= D_{wedge}\left(f, \beta_1, \theta_{1S}, \theta_{1R}, \tau, \tau_S + \tau_M, \tau_M, R_S + R_M, R_S, R_M + R_R, \hat{Z}_{1S}, \hat{Z}_{1R}\right) \\
\hat{D}_2(f) &= D_{wedge}\left(f, \beta_2, \theta_{2S}, \theta_{2R}, \tau, \tau_S + \tau_M, \tau_M, R_R, \tau_R, \ell, R_S + R_M, R_R, \hat{Z}_{2S}, \hat{Z}_{2R}\right)
\end{align*}
\]

The procedure described in this section for calculating the sound pressure at the receiver from sound propagation over two wedge-shaped screens will be referred to by the function \( p_{2wedge} \) as defined in Eq. (99).

\[
\begin{align*}
\hat{p}(f) &= p_{2wedge}\left(f, \beta_1, \theta_{1S}, \theta_{1R}, \beta_2, \theta_{2S}, \theta_{2R}, \tau_S, \tau_M, \tau_R, R_S, R_M, R_R, \hat{Z}_{1S}, \hat{Z}_{1R}, \hat{Z}_{2S}, \hat{Z}_{2R}\right)
\end{align*}
\]

5.7.4 Diffraction of a Thick Screen

This section describes the procedure used in the Nord2000 method to calculate the sound pressure at the receiver when sound propagates from a point source over a sceneen with two edges and finite impedance surfaces as shown in Figure 11. The edge closest to the source is designated the first edge \( T_1 \) and the edge closest to the receiver is designated the second edge \( T_2 \) in the description of the method. In the following \( R_1, R_2 \) and \( R_3 \) in the figure will be designated \( R_S, R_M, \) and \( R_R \). The procedure described in this section is based on the diffraction of two wedges. The first and second wedge is formed by the segments on each side of the top points \( T_1 \) and \( T_2 \), respectively. Therefore, \( T_1T_2 \) is included in both wedges.
The input variables in the model are:

- The travel time $\tau_S$ from source S to $T_1$
- The travel time $\tau_M$ from $T_1$ to $T_2$
- The travel time $\tau_R$ from receiver R to $T_2$
- The travel distance $R_S$ from S to $T_1$
- The travel distance $R_M$ from $T_1$ to $T_2$
- The travel distance $R_R$ from R to $T_2$
- The source diffraction angle $\theta_{1S}$ of the first wedge
- The “receiver” diffraction angle $\theta_{1R}$ of the first wedge. If $T_2$ is above the line from $T_1$ to R, then $\theta_{1R} = 0$. Otherwise $\theta_{1R}$ is the angle between the line $T_1T_2$ and the line $T_1R$
- Wedge angle $\beta_1$ of the first wedge
- Surface impedance $Z_{1S}$ of source face of the first wedge
- The “source” diffraction angle $\theta_{2S}$ of the second wedge. If $T_1$ is above the line from $T_2$ to S, then $\theta_{2S} = \beta_2$. Otherwise $\theta_{2S}$ is the angle between the receiver side face of the second wedge and the line $T_2S$
- The receiver diffraction angle $\theta_{2R}$ of the second wedge
- Wedge angle $\beta_2$ of the second wedge
- Surface impedance $Z_{2R}$ of receiver face of second wedge
In the method finite impedance at the top of the thick screen are ignored by assuming a hard top \((Z = \infty)\).

The total travel time \(\tau\) and distance \(\ell\) is defined in by Eqs. (100) and (101).

\[
\tau = \tau_S + \tau_M + \tau_R \\
\ell = R_S + R_M + R_R
\]  

(100)  

(101)

If the first edge is the most important edge the sound pressure at the receiver \(\hat{p}\) is calculated by Eq. (102).

\[
\hat{p}(f) = 0.5\hat{D}_1(f)\hat{D}_2(f)\frac{e^{ij2\pi f \tau}}{\ell}
\]

where

\[
\hat{D}_1(f) = D_{wedge}(f, \beta_1, \theta_{1S}, \theta_{1R}, \tau, \tau_S, \tau_M + \tau_R, \ell, R_S, R_M + R_R, \dot{Z}_{1S}, \infty) \\
\hat{D}_2(f) = D_{wedge}(f, \beta_2, \theta_{2S}, \theta_{2R}, \tau_M + \tau_R, \tau_M, R_M + R_R, R_M, \infty, \dot{Z}_{2R})
\]

(102)

If the second edge is the most important edge the sound pressure at the receiver \(\hat{p}\) is calculated by Eq. (103).

\[
\hat{p}(f) = 0.5\hat{D}_1(f)\hat{D}_2(f)\frac{e^{ij2\pi f \tau}}{\ell}
\]

where

\[
\hat{D}_1(f) = D_{wedge}(f, \beta_1, \theta_{1S}, \theta_{1R}, \tau_S + \tau_M, \tau_s, \tau_M + \tau_R, \ell, R_S, R_M + R_R, \dot{Z}_{1S}, \infty) \\
\hat{D}_2(f) = D_{wedge}(f, \beta_2, \theta_{2S}, \theta_{2R}, \tau_M + \tau_R, \tau_M, R_M + R_R, \infty, \dot{Z}_{2R})
\]

(103)

The procedure described in this section for calculating the sound pressure at the receiver from sound propagation over a thick screen will be referred to by the function \(p2edge\) as defined in Eq. (104).

\[
\hat{p}(f) = p2edge(f, \beta_1, \theta_{1S}, \theta_{1R}, \beta_2, \theta_{2S}, \theta_{2R}, \tau_S, \tau_R, \tau_M, R_S, R_M, R_R, \dot{Z}_{1S}, \dot{Z}_{2R})
\]

(104)

### 5.7.5 Wedge with a Non-Reflecting Surface

In the some cases where the wedge faces are assumed to be non-reflecting (shadow zone shielding, finite screens) the method described in Section 5.7.1 will be simplified. The diffracted sound pressure given by Eq. (78) will change to Eq. (105) and the possible contribution from a reflection in a wedge face given by either Eq. (89) or (90) disappears.
\[
\hat{p}_{\text{diff}}(f) = -\frac{1}{\pi} A(\theta_i) \hat{E}_v (A(\theta_i)) e^{i\omega \tau} \frac{e^{i\omega \tau}}{\ell}
\]  

(105)

The procedure for calculating the sound pressure and the diffraction coefficient of a non-reflecting wedge are referred to by the functions \( p_{\text{wedge}0} \) and \( D_{\text{wedge}0} \) defined in Eqs. (106) and (107).

\[
\hat{p}(f) = p_{\text{wedge}0}(f, \beta, \theta_S, \theta_R, \tau, \tau_S, \tau_R, \ell, R_S, R_R)
\]  

(106)

\[
\hat{D}(f) = D_{\text{wedge}0}(f, \beta, \theta_S, \theta_R, \tau, \tau_S, \tau_R, \ell, R_S, R_R)
\]  

(107)

5.8 Fresnel Zones, Fresnel-Zone Weights and Fresnel-Zone Interpolation

The concept of Fresnel-zones is widely used in the Nord2000 propagation model. Particularly when sound is reflected by a plane surface the efficiency of the reflection is quantified by the ratio between the area of the surface within the Fresnel-zone and the area of the entire Fresnel-zone. This ratio is called the Fresnel-zone weight.

The Fresnel ellipsoid is defined by the locus of the points \( P \) defined by Eq. (108) where \( S \) is the source point, \( R \) is the receiver point, and \( F_\lambda \) is a fraction of the wavelength \( \lambda \). The foci of the ellipsoid are placed at \( S \) and \( R \).

\[
|SP| + |RP| - |SR| = F_\lambda \lambda
\]  

(108)

When the sound field is reflected by a plane surface, the Fresnel-zone is defined by the intersection between the plane and the Fresnel ellipsoid with foci at the image source point \( S' \) and the receiver \( R \) as shown in Figure 12.

![Figure 12](image_url)

*Figure 12*  
*Definition of Fresnel ellipsoid and Fresnel-zone.*
For practical purposes the elliptical shape is very inconvenient to work with when calculating sub-areas within the Fresnel-zone. In the Nord2000 method the Fresnel-zone is therefore defined to be the circumscribed rectangle instead. The size of the rectangle is determined by the size of the ellipse along the major and minor axes (in the direction of propagation and perpendicular to the direction). Another practical modification of the Fresnel-zone definition is that only the part of the Fresnel-zone area between source and receiver is included.

As the propagation model is two-dimensional in most of the Nord2000 method the Fresnel-zone becomes one-dimensional as shown in Figure 13.

![Figure 13](image)

**Figure 13**

*Definition of the one-dimensional Fresnel-zone (P1P2) in the two-dimensional part of the propagation model.*

The position of the Fresnel-zone and the Fresnel-zone weights can be determined by a number of auxiliary functions *CalcFZd, FresnelZoneSize, FresnelZoneW, and FresnelZoneWm.*

The fraction $F_z$ used when calculating the Fresnel-zone weight depends on the sub-model. When calculating terrain effects $F_z = 1/16$ is used except in the flat terrain model with more than one ground type where $F_z = 1/4$ is used. In case of reflections by vertically erected surfaces and when determining the efficiency of a scattering zone with finite size $F_z = 1/8$ is used.

In several of the sub-models in the Nord2000 method for calculating terrain effects, a principle has been used which is denoted Fresnel-zone interpolation. In the Fresnel-zone interpolation principle it is assumed that the overall terrain effect can be determined on basis of the terrain effect $\Delta L_i(f)$ calculated for each segment separately disregarding the finite size of the segment. The overall effect $\Delta L(f)$ is determined by adding the terrain effects of all segments weighted by the Fresnel-zone weight $w_i(f)$ of the segment as shown in Eq. (109).
\[
\Delta L(f) = \sum_{i}^{N} w_i(f) \Delta L_i(f)
\]  

(109)

In Sub-model 3 (non-flat terrain without screening effects) described in Section 5.12 the Fresnel-zone weight in a frequency band \( w_i(f) \) is normalized to a sum of 2 if the sum exceeds 2. The weight in a frequency band is also normalized in case of large attenuation (small values of \( \Delta L \)) as described in Section 5.12.

In Sub-models 4-6 (terrain with one or two screens) described in Sections 5.13 through 5.15 the Fresnel-zone weight in a frequency band \( w_i(f) \) is again normalized if the sum of weights exceeds a given value in the same way as in sub-model 3. However, in this case the normalization is based on the sum of weights in excess of 1 in each terrain region (before, after or between screens). If the sum of excess values exceeds 1 the weights are normalized as described in Sections 5.13 through 5.15.

5.9 Coherence Coefficients

The coherence between two rays in propagation model is determined by a frequency dependent variable denoted a coherence coefficient. Coherence coefficients are denoted \( F \) and is for each frequency band a real number between 0 and 1. The value 1 is indicating full coherence and the value 0 is indicating no coherence. The overall coherence coefficient \( F \) is a combination of different coherence effects as shown in Eq. (110).

\[
F = F_f F_{\Delta \tau} F_c F_r F_s
\]  

(110)

where

- \( F_f \) is a coherence coefficient due to averaging within the one-third octave band
- \( F_{\Delta \tau} \) is a coherence coefficient due to fluctuating refraction (\( s_A > 0 \) or \( s_B > 0 \))
- \( F_c \) is a coherence coefficient due to turbulence (\( C_v^2 > 0 \) or \( C_T^2 > 0 \))
- \( F_r \) is a coherence coefficient due to ground surface roughness (\( r > 0 \))
- \( F_s \) is a coherence coefficient due to propagation through scattering zones

Calculation of \( F_f, F_{\Delta \tau}, F_c, \) and \( F_r \) are described in the following section whereas the calculation of \( F_s \) is described in Section 5.19.

5.9.1 Coherence Coefficient due to Frequency Band Averaging

The value of coherence \( F_f \) due to frequency band averaging depends on the travel time difference \( \Delta \tau(f) \geq 0 \) between the secondary ray and the primary ray and on the frequency \( f \) ans is calculated as shown in Eq. (111).
\[ F_f(f, \Delta \tau) = \begin{cases} 1 & x = 0 \\ \frac{\sin x}{x} & 0 < x < \pi \\ 0 & x \geq \pi \end{cases} \]  
\text{where}\ x = 0.23\pi f \Delta \tau(f)  
\hspace{1cm} (111)

5.9.2 Coherence Coefficient due to Fluctuating Refraction

The value of coherence due to fluctuating refraction \( F_\Delta \), depends on the travel time difference \( \Delta \tau(f) \geq 0 \) in case of average refraction (based on weather variables \( A \) and \( B \)) and on the travel time difference \( \Delta \tau_v(f) \geq 0 \) in case of upper refraction (based on \( A_v \) and \( B_v \)) between the secondary ray and the primary ray and on the frequency \( f \) and is calculated as shown in Eq. (112).

\[ F_\Delta(f, \Delta \tau, \Delta \tau_v) = \begin{cases} 1 & x = 0 \\ \frac{\sin x}{x} & 0 < x < \pi \\ 0 & x \geq \pi \end{cases} \]  
\text{where}\ x = 2\pi f |\Delta \tau_v(f) - \Delta \tau(f)|  
\hspace{1cm} (112)

5.9.3 Coherence Coefficient due to Turbulence

The value of coherence due to turbulence \( F_c \) depends on the turbulence variables \( C_v^2 \) and \( C_f^2 \), the average temperature \( \bar{t} \), the average sound speed \( \bar{c} \), the transversal separation \( \rho \), the horizontal distance \( d \), and the frequency \( f \) and is calculated as shown in Eq. (113). \( \exp' \) is the auxiliary function defined in Section 5.23.3.

\[ F_c(f, C_v^2, C_f^2, \bar{t}, \bar{c}, \rho, d) = \exp'(x) \]  
\text{where}\ x = -5.3888 \left( \frac{C_f^2}{(\bar{t} + 273.15)} + \frac{22 C_v^2}{3 \bar{c}^2} \right) \left( \frac{f}{\bar{c}} \right)^2 \rho^{5/3} d  
\hspace{1cm} (113)

5.9.4 Coherence Coefficient due to Ground Surface Roughness

The value of coherence due to ground surface roughness \( F_r \) depends on the wave number \( k \), the grazing reflection angle \( \psi_G \), and the ground surface roughness \( r \) and is calculated as shown in Eq. (114). \( \exp' \) is the auxiliary function defined in Section 5.23.3.
\[ F_r(k, \psi_G, r) = \exp(0.5 \, g(X)) \]

where

\[
g(X) = \begin{cases} 
0 & X \leq 0.026686 \\
0.55988 \, (0.115448 - X) - 0.049696 & 0.026686 < X < 0.115448 \\
-0.066 + 1.066 \, X - 8.543 \, X^2 + 4.71 \, X^3 - 0.83 \, X^4 & X \geq 0.115448
\end{cases}
\] (114)

and

\[ X = k \, r \sin(\psi_G) \]

### 5.10 Sub-Model 1: Flat Terrain with One Type of Surface

The geometrical setup in case of flat terrain with one type of surface is shown in Figure 14. The rays shown in the figure are straight line corresponding to a non-refracting atmosphere (\( \xi = 0 \)). For refracting atmospheres the rays will be arcs of circles instead as described in Section 5.5.

![Geometrical variables for flat terrain](image)

**Figure 14**

*Geometrical variables for flat terrain.*

The input variables of the sub-model are:

- Shortest distance \( h_s \) from the source S to the ground surface
- Shortest distance \( h_R \) from the receiver R to the ground surface
- Distance \( d \) from S to R measured along the ground surface
- Flow resistivity \( \sigma \) of the ground
- Roughness \( r \) of the ground
- Roughness length \( z_0 \)
• Weather variables $A, B, C, s_A, s_B$

• Turbulence variables $C_r^2, C_T^2$

First the modified frequency dependent equivalent linear sound speed profile is determined by the function $CalcEqSSPGround$ described in Section 5.5.3 as shown in Eq. (115) for average refraction and for upper refraction (indicates by $+$).

\[
\begin{align*}
(\xi(f), c_0(f), \bar{c}, \xi, c_0) &= CalcEqSSPGround(h_S, h_R, \bar{Z}_G(f), z_0, A, B, C) \\
(\xi_\tau(f), c_0, (f), NA, NA, NA) &= CalcEqSSPGround(h_S, h_R, \bar{Z}_G(f), z_0, A_+, B_+, C)
\end{align*}
\] (115)

The ray variables are determined for the direct ray and the reflected ray in Eq. (116) for average refraction and upper refraction using the procedures $DirectRay$ and $ReflectedRay$ described in Sections 5.5.4 and 5.5.5. $NA$ indicates that a calculated variable is not used. If the calculation by $DirectRay$ shows that the receiver is in a shadow zone ($\xi < 0$ and $d > 0.95 \ d_{SZ}$ where $d_{SZ}$ is defined in Section 5.5.4) calculations by $ReflectedRay$ are not carried out. The variables $\xi, c_0, r, \psi_G$, and $\Delta r$ are in the following equations of this section a function of the frequency.

\[
\begin{align*}
(\tau_1, R_1, NA, \bar{c}, d_{SZ}) &= DirectRay(d, h_S, h_R, \xi, c_0) \\
(\tau_1_, NA, NA, NA, NA) &= DirectRay(d, h_S, h_R, \xi_\tau, c_0_\tau) \\
(\tau_2, R_2, NA, NA, NA, NA, \psi_G, NA) &= ReflectedRay(d, h_S, h_R, \xi_\psi, c_0) \\
(\tau_2_, NA, NA, NA, NA, NA, NA, NA) &= ReflectedRay(d, h_S, h_R, \xi_\psi_, c_0_\tau)
\end{align*}
\] (116)

The travel time differences $\Delta \tau$ and $\Delta \tau_\tau$ for average and upper refraction are determined by Eq. (117).

\[
\begin{align*}
\Delta \tau &= TravelTimeDiff (\tau_2, \tau_1) \\
\Delta \tau_\tau &= TravelTimeDiff (\tau_2_, \tau_1_\tau)
\end{align*}
\] (117)

The coherence coefficients $F$ is calculated by Eq. (118) where the coherence coefficients $F_f, F_{\Delta \tau}, F_{\tau}$, and $F_{\psi}$ are calculated as described in Section 0. $\rho$ is the transversal separation calculated by Eq. (119) and $k_0$ is the wave number at the ground. In case of propagation through a scattering zone the coherence coefficient $F_s$ is calculated as described in Section 5.19. Otherwise $F_s = 1$.

\[
F(f) = F_f(f, \Delta \tau)F_{\Delta \tau}(f, \Delta \tau, \Delta \tau_\tau)F_{\tau}(f, C_r^2, C_T^2, t_{mean}, \bar{c}, \rho, d)F_{\psi}(k_0, \psi_G, r)F_s(f) \] (118)

\[
\rho = \frac{2h_S h_R}{h_S + h_R} \] (119)

If the receiver is not in a shadow zone the ground effect $\Delta L_{\text{flat}}$ is calculated by Eq. (120).
\[
\Delta L_{\text{flat}}(f) = \left[ 1 + F \frac{R_1}{R_2} e^{i2\pi f T} \hat{Q}(f, \tau_2, \psi_G, \hat{Z}_G) \right]^2 + \left( 1 - F^2 \frac{R_1}{R_2} \Re \left( f, \hat{Z}_G \right) \right)^2
\]

(120)

Otherwise, if the receiver is in a shadow zone the ground effect \( \Delta L_{\text{flat}} \) is calculated by Eq. (121).

\[
\Delta L_4(f) = \left( 1 + F \hat{Q}(f, 0, 0, \hat{Z}_G) \right)^2 + \left( 1 - F^2 \Re(f, \hat{Z}_G) \right)^2 + \Delta L_{SZ}(f)
\]

(121)

In Eq. (121) the term \( \Delta L_{SZ} \) is the part of the shadow zone attenuation that is called the shadow zone shielding in the Nord2000 method. \( \Delta L_{SZ} \) is calculated as shown in Eq. (122) by the auxiliary function \( \text{ShadowZoneShielding} \) based on the variables \( d, h_S, h_R, \xi, c_0 \) and \( d_{SZ}, \xi \) and \( c_0 \) are the frequency independent variables obtained by the function \( \text{CalcEqSSPGround} \).

\[
\Delta L_{SZ}(f) = \text{ShadowZoneShielding}(f, d, h_S, h_R, \xi, c_0, d_{SZ})
\]

(122)

If Sub-model 1 is applied for a non-flat terrain the values of \( h_{S}, h_{R} \) and \( d \) measured relative to the equivalent flat terrain and calculated as shown in Eq. (316) are used instead of \( h_{S}, h_{R} \) and \( d \).

Sub-model 1 is used by other sub-models of the Nordtest standard method. In these cases Sub-model 1 is referred to by the function \( \text{SubModel1} \) as defined in Eq. (123).

\[
\Delta L_i(f) = \text{SubModel1}(d_i', h_{S,i}', h_{R,i}', \sigma_i, r_i, z_0, A, B, C, s_A, s_B, C_v, C_T^2)
\]

(123)

5.11 Sub-Model 2: Flat Terrain with more than One Type of Surface

If the terrain is flat but have more than one type of ground surface (combination of flow resistivity \( \sigma \) and roughness \( r \)) Sub-model 1 cannot be used. In this case the ground effect \( \Delta L_2 \) is calculated by Sub-model 2. The input variables of Sub-model 2 are:

- Shortest distance \( h_S \) from the source S to the ground surface
- Shortest distance \( h_R \) from the receiver R to the ground surface
- Distance \( d_i \) from S to the end point of ground segment no. i measured along the ground surface (\( d_{i-1} \) is the distance from S to the starting point of the segment, and \( d_0 = 0 \))
- Flow resistivity \( \sigma_i \) of ground segment no. i
- Roughness \( r_i \) of ground segment no. i
• Roughness length $z_0$  
• Weather variables $A, B, C, s_A, s_B$  
• Turbulence variables $C_v^2, C_T^2$

The ground effect according to Sub-model 2 is determined by Eq. (124) where $N_\sigma$ is the number of impedances and $N_r$ is the number of roughness types. $\Delta L_{ii,ir}(f)$ is the ground effect for each combination of $\sigma$ and $r$ calculated by Sub-model 1 as described in Section 5.10 and $w'_{ii,ir}(f)$ is a modified Fresnel-zone weight quantifying the relative importance of each ground type in this sub-model.

$$\Delta L_2(f) = \sum_{ii}^{N_\sigma} \sum_{ir}^{N_r} w_{ii,ir}(f) \Delta L_{ii,ir}(f)$$

(124)

The geometrical variables used to calculate the modified Fresnel-zone weight $w_{ii,ir}(f)$ for each ground segment are defined in Figure 15. Other variables used in the calculation are the product $F_3 \lambda$ (where $F_3$ in this submodel is equal 0.25 and $\lambda$ is the wavelength) and the relative sound speed gradient $\zeta$ and the sound speed at the ground $c_0$ in the equivalent linear sound speed profile.

Figure 15
Geometrical variables used in the calculation of the Fresnel-zone weight for one ground segment.
The Fresnel-zone weight \( w_i(f) \) for the \( i \)’th ground segment (out of \( N_s \)) to be used at low frequencies is calculated by Eq. (125) based on the auxiliary function \( \text{FresnelZoneW} \). The function also calculates the horizontal distance and the source and receiver heights corresponding to the refraction modified source and receiver positions defined in Section 5.23.7. The correction for refraction is indicated by placing the symbol \( \hat{\sigma} \) over the variables.

\[
(w_i(f), \hat{a}, \hat{h}_S, \hat{h}_R, \text{NA}) = \text{FresnelZoneW}(d, h_S, h_R, d_{i-1}, d_i, 0.25\lambda, \xi, c_0)
\]  \hspace{1cm} (125)

A special Fresnel-zone weight \( r_i(f) \) to be used at high frequencies is calculated by the function \( \text{FresnelZoneWm} \) as shown in Eq. (126).

\[
r_i(f) = \text{FresnelZoneWm}(d, h_S, h_R, d_{i-1}, d_i, 0.25\lambda, \xi, c_0) \hspace{1cm} (126)
\]

For each type of surface (each combination of flow resistivity \( ii \) and ground roughness \( ir \)) the weights from all segments are added as shown in Eq. (127). The weight \( w_{ii,ir,L} \) is the Fresnel-zone weight in the low frequency range whereas \( r_{ii,ir} \) is a weight used to calculate the Fresnel-zone weight \( w_{ii,ir,H} \) in the high frequency range.

\[
w_{ii,ir,L}(f) = \sum_{i}^{N_s} \begin{cases} w_i(f) & \text{if } \# of \sigma = ii \land \# of \tau = ir \\ 0 & \text{otherwise} \end{cases}
\]

\[
r_{ii,ir}(f) = \sum_{i}^{N_s} \begin{cases} r_i(f) & \text{if } \# of \sigma = ii \land \# of \tau = ir \\ 0 & \text{otherwise} \end{cases}
\]  \hspace{1cm} (127)

On basis of \( r_{ii,ir} \) the weight \( w_{ii,ir,H} \) in the high frequency range can be calculated by Eq. (128) where \( \psi_G \) is the grazing reflection angle. Most of the variables in the equation are a function of the frequency although not indicated.

\[
r_i = \sum_{ir}^{N_s} r_{ii,ir}
\]

\[
r_i^* = 8.78 r_i^5 - 21.95 r_i^4 + 21.76 r_i^3 - 10.69 r_i^2 + 3.1 r_i
\]

\[
r_{ii,ir} = \frac{r_{ii,ir}}{\sum_{ii}^{N_s} r_{ii}}
\]

\[
r_i = \begin{cases} 1 & \tan\psi_G \geq 0.04 \\ \log \left( 200 \tan\psi_G \right) / \log (8) & 0.005 < \tan\psi_G < 0.04 \\ 0 & \tan\psi_G \leq 0.005 \end{cases}
\]

\[
w_{ii,ir,H}(f) = (r_{ii,ir} - r_{ii,ir}^*) r_i + r_{ii,ir}^*
\]
Then the modified Fresnel-zone weight \( w'_{i,i,r}(f) \) is calculated in the whole frequency by Eq. (129).

\[
\begin{align*}
  w'_{i,i,r}(f) &= \begin{cases} 
    w_{i,i,r,L}(f) & f \leq f_L \\
    \log \frac{f_H - f}{f_L} \left( w_{i,i,r,L}(f) - w_{i,i,r,H}(f) \right) + w_{i,i,r,H}(f) & f_L < f < f_H \\
    w_{i,i,r,H}(f) & f \geq f_H
  \end{cases}
\end{align*}
\] (129)

The frequencies \( f_L \) and \( f_H \) are determined on basis of phase differences \( \alpha_L \) and \( \pi \) between the direct and reflected ray as shown in Eqs. (130) and (131). The calculation is carried using the auxiliary function \( \text{PhaseDiffFreq} \) described in Section 5.23.12. \( Z_{G,\text{min}}(f) \) is the terrain impedance corresponding the smallest flow resistivity in the terrain profile and the \( c_0 \) is the sound speed at the ground in the equivalent linear sound speed profile.

\[
\begin{align*}
  f_L &= \text{PhaseDiffFreq}(\bar{d}, \tilde{h}_S, \tilde{h}_R, \bar{Z}_{G,\text{min}}(f), c_0, \alpha_L) \\
  f_H &= \text{PhaseDiffFreq}(\bar{d}, \tilde{h}_S, \tilde{h}_R, \bar{Z}_{G,\text{min}}(f), c_0, \pi)
\end{align*}
\] (130, 131)

The phase difference \( \alpha_L \) is determined by Eq.(132).

\[
\Delta \alpha_L = \pi - (1.9483 \ln (h_{\text{min}}) + 18.052) \tan \psi_G
\]
where
\[
h_{\text{min}} = \max\left(\min(h_S, h_R), 0.01\right)
\] (132)

If \( f_L > 0.8 f_H, f_L = 0.8 f_H \) is used instead.

If Sub-model 2 is applied for a non-flat terrain the values of \( h_{S,e}, h_{R,e} \) and \( d_e \) measured relative to the equivalent flat terrain and calculated as shown in Eq. (316) are used instead of \( h_S, h_R \) and \( d \). The value \( d_{e,i} \) determined by Eq. (133) for the projection of ground point no. \( i \) onto the equivalent flat terrain is used instead of \( d_i \) (other variables in Eq. (133) correspond to Eq. (316)). If \( d_{i+1} \leq d_i \) segment no. \( i \) is not included in the Sub-model 2 calculations.

\[
\begin{align*}
  \left(x'_{Ge,i}, z'_{Ge,i}, NA\right) &= \text{NormLine}(x_{SGe}, z_{SGe}, x_{BGe}, z_{BGe}, x_i, z_i) \\
  d_{e,i} &= \text{Length}(x'_{SGe}, z'_{SGe}, x'_{Ge,i}, z'_{Ge,i})
\end{align*}
\] (133)
5.12 Sub-Model 3: Non-Flat Terrain without Screening Effects

If the terrain is non-flat but contains neither screens nor parts of the terrain that can cause screening effects, the terrain effect is calculated by Sub-model 3 described in this section. When to use Sub-model 3 is described in Sections 5.2.1 and 5.2.1.6. An example of such a terrain which in most cases will form a “valley-shape” is shown in Figure 16. The figure also shows the source and receiver heights $h_S$ and $h_R$.

![Diagram](image)

*Figure 16*

*Example of a segmented terrain without screening effects.*

The input variables of the sub-model correspond to the input variables defined in Sections 5.3.1 and 5.3.2.

In Sub-model 3 it is assumed that the overall terrain effect can be determined by calculating the terrain effect for each segment separately and then adding them according to the Fresnel-zone interpolation principle described in Section 5.8.

When calculating the terrain effect of each segment it is necessary to distinguish between three types of terrain segments:

- Concave segments
- Convex segments
- Transition segments

The type of segment is determined on basis of the source and receiver heights $h'_S$ and $h'_R$ measured relative to the extended segment. If the source or receiver is below the segment this is indicated by a negative value. Figure 17 shows examples of the three types of segments taken from Figure 16 and shows how the variables $h'_S$ and $h'_R$ and the horizontal distance $d'$ are defined. These variables are used when calculating the terrain effect of each segment. The variables $h'_S$ and $h'_R$ relative to $h_S$ and $h_R$ defined in Section 5.4.1 are used to define the type of terrain segment as described below.
Figure 17
Definition of source and receiver heights $h'_S$ and $h'_R$ relative to the extended segment for
a) a concave segment where $h'_S > h_S$ and $h'_R > h_R$  b) a convex segment where $h'_S > h_S$
and $h'_R < 0$ and  c) a transition segment where $0 < h'_S < h_S$ and $h'_R > h_R$.

The type of segment is determined on basis of the so-called relative source and receiver
height $h_{S,rel}(f)$ and $h_{R,rel}(f)$ which will be defined in the following. The relative heights are a
function of the frequency. These heights are in case of a concave or transition segment
calculated on basis of the refraction corrected source and receiver height. The refraction
corrected variables are indicated by the symbol $\cup$ over the variables and are calculated by
the function $FresnelZoneW$ as shown in Eq. (134). $d_{i-1}$ and $d_i$ are the distances from the
source to the start and end point of the segment measured along the segment as shown in Figure 15. The Fresnel-zone weight $w_i(f)$ also calculated by the function $FresnelZoneW$ is used only for a concave and a transition segment. $\lambda$ is the wavelength and $\xi$ and $c_0$ defining the equivalent linear sound speed profile are calculated by Eq. (135).

\[
(w_i(f), \tilde{d}', \tilde{h}_S', \tilde{h}_R', d_{refl}) = FresnelZoneW(d', h_S', h_R', d_{i-1}, d_i, 1/16 \lambda, \xi, c_0)
\]  
(134)

\[
(\xi, c_0, NA) = CalcEqSSP(h_S', h_R', z_0, A, B, C)
\]  
(135)

The type of segment is determined on basis of the relative source height $h_{S,rel}$ and the relative receiver height $h_{R,rel}$ defined as shown in Eqs. (136) and (137). If the segment is a convex segment $\tilde{h}_S' = h_S'$ and $\tilde{h}_R' = h_R'$. If the heights $h''_S$ and $h''_R$ are the minimum allowable heights of a concave segment. $h''_S$ is determined by the smallest value of the source height $h_S$ and a height called $h_{S,Fz}$ and in the same way $h''_R$ is determined by the smallest value of the receiver height $h_R$ and a height called $h_{R,Fz}$. The heights $h_{S,Fz}$ and $h_{R,Fz}$ are calculated by the auxiliary function $MinConcaveHeight$ as shown in Eq. (138) and (139). $d_{refl}$ is the distance from source to reflection point measured along the segment.

\[
h_{S,rel}(f) = \begin{cases} 
1 & \tilde{h}_S' \geq h_S'' \\
\frac{\tilde{h}_S'}{h_S'(f)} & 0 < \tilde{h}_S' < h_S'' \\
0 & \tilde{h}_S' \leq 0 
\end{cases}
\]  
(136)

where

\[
h_S''(f) = \min \left(h_S, h_{S,Fz}(f)\right)
\]

\[
h_{R,rel}(f) = \begin{cases} 
1 & \tilde{h}_R' \geq h_R'' \\
\frac{\tilde{h}_R'}{h_R'(f)} & 0 < \tilde{h}_R' < h_R'' \\
0 & \tilde{h}_R' \leq 0 
\end{cases}
\]  
(137)

where

\[
h_R''(f) = \min \left(h_R, h_{R,Fz}(f)\right)
\]

\[
h_{S,Fz}(f) = MinConcaveHeight(\tilde{h}_R', \tilde{d}_s, \tilde{d}, \lambda)
\]

where

\[
\tilde{d}_s = d_{i-1} - d_{refl} + \tilde{d}_{refl}
\]  
(138)
\[ h_{R,rel}(f) = \text{MinConcaveHeight}(h'_S, \bar{d}, \tilde{d}, \lambda) \]  
where  
\[ \bar{d} = d - d_i + d_{refl} - \tilde{d}_{refl} \]

The type of segments can now be determined on basis of \( h_{S,rel} \) and \( h_{R,rel} \):

- Concave segment: \( h_{S,rel}(f) = 1 \land h_{R,rel}(f) = 1 \)
- Convex segment: \( h_{S,rel}(f) = 0 \lor h_{R,rel}(f) = 0 \)
- Transition: if neither concave nor convex

If the ground segment is a concave segment the terrain effect is calculated by Eq. (140) where the function \( \text{SubModel1} \) designates Sub-model 1 described in Section 5.10 and the Fresnel-zone weight \( w_i(f) \) of the segment is calculated as shown in Eq. (134).

\[ \Delta L_s(f) = \text{SubModel1}\left(d'_i, h'_{S,j}, h'_{R,j}, \sigma_j, r_j, z_0, A, B, C, s_A, s_B, C_f^2, C_l^2\right) \]  

(140)

If the ground segment is a convex segment the terrain effect has to be calculated using the diffraction solution described in Section 5.7.1. The convex segment will constitute of one of the wedge faces or be a part of one of the wedge faces which is denoted the primary wedge face. The secondary wedge face will geometrically be determined by another segment in the terrain profile as described in the following but will in the calculation be assigned the same impedance.

If \( h_{S,rel} < h_{R,rel} \), the secondary wedge face will be determined by a secondary ground segment between the source and the convex segment under consideration. The secondary ground segment to be used is the segment closest the convex segment where \( h'_{Sv} \geq h'_{Sv} \). \( h'_{Sv} \) is the source height measured vertically about the secondary segment.

If \( h_{S,rel} \geq h_{R,rel} \), the secondary wedge face will be determined by a secondary ground segment between the receiver and the convex segment under consideration. The secondary ground segment to be used is the segment closest the convex segment where \( h'_{Rv} \geq h'_{Rv} \). \( h'_{Rv} \) is the receiver height measured vertically about the secondary segment.

If the two segments are not adjacent, an equivalent wedge is determined. The top of the wedge is determined by the intersection between the primary and secondary segment as shown in Figure 18. The coordinates of the top point \((x_T,z_T)\) are calculated by the auxiliary function \( \text{WedgeCross} \) as shown in Eq. (141). \((x_1, z_1)\) and \((x_2, z_2)\) are the start and end coordinates of the segment closest to the source and \((x_3, z_3)\) and \((x_4, z_4)\) are the start and end coordinates of the segment closest to the receiver \((x_1 < x_2 < x_3 < x_4)\).
Considered convex segment

Secondary wedge segment

Figure 18
Definition of an equivalent wedge used for predicting the ground effect of a convex segment.

\[(x_T, z_T) = \text{WedgeCross}(x_1, z_1, x_2, z_2, x_3, z_3, x_4, z_4)\]  \hspace{1cm} (141)

If the two segments are adjacent, the wedge is directly determined by the primary and secondary segment and \(x_T = x_2 = x_3\) and \(z_T = z_2 = z_3\).

In order to determine the diffraction angles of the wedge, the height of the source \(h'_{S1}\) above the source side wedge face and the distance \(d'_1\) from source to the top of the wedge measured along the wedge face are determined by Eqs. (142) and (143). In the same way the height of the receiver \(h'_{R2}\) above the receiver side wedge face and the distance \(d'_2\) from receiver to the top of the wedge measured along the wedge face are determined by Eqs. (144) and (145). Also the equivalent screen height \(h''_{SCR}\) is determined by Eq. (22) in Section 5.5.2.

\[(x'_S, z'_S, h'_{S1}) = \text{NormLine}(x_1, z_1, x_T, z_T, x_S, z_S)\]  \hspace{1cm} (142)

\[d'_1 = \text{Length}(x'_S, z'_S, x_T, z_T)\]  \hspace{1cm} (143)

\[(x'_R, z'_R, h'_{R2}) = \text{NormLine}(x_T, z_T, x_4, z_4, x_R, z_R)\]  \hspace{1cm} (144)

\[d'_2 = \text{Length}(x'_R, z'_R, x_T, z_T)\]  \hspace{1cm} (145)

The next step is to calculate the wedge angle \(\beta\) and the diffraction angles \(\theta_S\) and \(\theta_R\) as shown in Eq. (146). The variables \(\Delta\theta_S\) and \(\Delta\theta_R\) which are the change in diffraction angles due to refraction are calculated in Eq (148) and (150).
The travel time $\tau_S$ between source and wedge top and $\tau_R$ between receiver and wedge top and the corresponding travel distances $R_S$ and $R_R$ are calculated by Eqs. (147) to (150).

\[
\left( \xi_S, c_{0S}, NA \right) = \text{CalcEqSSP} \left( h'_{SI}, h^*_{SCR}, z_0, A, B, C \right) \tag{147}
\]

\[
\left( \tau_S, R_S, \Delta \theta_S, NA, NA \right) = \text{DirectRay} \left( d'_i, h'_{i}, 0, \xi_S, c_{0S} \right) \tag{148}
\]

\[
\left( \xi_R, c_{0R}, NA \right) = \text{CalcEqSSP} \left( h^*_{SCR}, h'_{R1}, z_0, A, B, C \right) \tag{149}
\]

\[
\left( \tau_R, R_R, \Delta \theta_R, NA, NA \right) = \text{DirectRay} \left( d'_i, 0, h'_{R}, \xi_S, c_{0S} \right) \tag{150}
\]

The terrain effect of a convex segment can finally be calculated by Eq. (151) using the auxiliary function $p_{\text{wedge}}$. $R_{SR}$ is the source-receiver distance and $\hat{Z}_i(f)$ is the impedance of the convex segment.

\[
\Delta L_i (f) = 20 \log \left( \left| \hat{p}(f) \right| R_{SR} \right)
\]

where

\[
\hat{p}(f) = p_{\text{wedge}} \left( f, \beta, \theta_S, \theta_R, \tau_S + \tau_R, R_S + R_R, R_R, \hat{Z}_i(f), \hat{Z}_i(f) \right)
\]

For a convex segment the Fresnel-zone weight $w_i(f)$ cannot be calculated by the procedure described in 5.8 as the source or the receiver is below the segment. Instead a modified principle is applied. If the top point of the wedge is at or above the terrain base line defined in Section 5.3.1, the projection of the convex segment onto the base line is used when determining the Fresnel-zone weight (similar to a concave segment). If the top point is below the base line the projection on a line parallel with the base line through the top point is used instead as shown in Figure 19. If the considered segment is $P_i P_0$ the segment
used in the determination of the Fresnel-zone weight is $P'_1P_0$ and if the considered segment is $P_0P_2$ the segment to be used is $P_0P'_2$.

\begin{figure}
\centering
\includegraphics[width=\textwidth]{figure19}
\caption{Definition of the Fresnel-zone weighting principle for convex segments.}
\end{figure}

The geometrical variables in the modified Fresnel-zone principle described above can be calculated as shown in Eq. (152).

\begin{align}
(x'_1, z'_1, h'_S) &= \text{NormLine}(x'_SG, z'_SG, x'_RG, z'_RG, x'_S, z'_S) \\
(NA, NA, h'_R) &= \text{NormLine}(x'_SG, z'_SG, x'_RG, z'_RG, x'_R, z'_R) \\
(x'_1, z'_1, h'_1) &= \text{NormLine}(x'_iSG, z'_iSG, x'_iRG, z'_iRG, x'_i, z'_i) \\
(x'_2, z'_2, h'_2) &= \text{NormLine}(x'_iSG, z'_iSG, x'_iRG, z'_iRG, x'_{i+1}, z'_{i+1}) \\
\Delta h &= \begin{cases}
|h'_m| & h'_m < 0 \\
0 & h'_m \geq 0
\end{cases}

h'_S = h'_S + \Delta h \\
h'_R = h'_R + \Delta h
\end{align}

Accordingly the Fresnel-zone weight $w_i(f)$ can be calculated by Eqs. (153) where the Fresnel-zone weight is further modified if both $h_{S,rel}$ and $h_{R,rel}$ are less than one. $\lambda$ is the wave-
length and $\xi'$ and $c'_0$ defining the equivalent linear sound speed profile are calculated by Eq. (154).

$$w_{i,j}(f), NA, NA, NA, NA = FresnelZoneW(d', h'_S, h'_R, d'_{i-1}, d'_i, 1/16 \lambda, \xi', c'_0)$$

$$w_i(f) = w_{i,j}(f)Max(h_{S,rel}(f), h_{R,rel}(f))$$

$$w_{i,j}(f), NA, NA, NA, NA = FresnelZoneW(d', h'_S, h'_R, d'_{i-1}, d'_i, 1/16 \lambda, \xi', c'_0)$$

(153)

(154)

If the segment is a transition segment the terrain effect and the Fresnel-zone weight is calculated by the method for a concave as well as a convex segment and the results is obtained by interpolation between the two results as shown in Eq. (155). $w_{i,concave}$ and $\Delta L_{i,concave}$ are determined by Eqs. (134) and (140), respectively and $w_{i,convex}$ and $\Delta L_{i,convex}$ by Eqs. (153) and (151).

$$w_i(f)\Delta L_i(f) = w_{i,concave}(f)\Delta L_{i,concave}(f)r(f) + w_{i,convex}(f)\Delta L_{i,convex}(f)(1-r(f))$$

$$where$$

$$r(f) = Min(h_{S,rel}(f), h_{R,rel}(f))$$

(155)

Finally, the over-all terrain effect $\Delta L_3$ for Sub-model 3 of the $N_0$ terrain segments can be calculated by Eq. (156) using a modified Fresnel-zone interpolation principle. The modified principle is based on the original Fresnel-zone interpolation result $\Delta L_0$ calculated as described in Section 5.8. When $\Delta L_0$ is greater than zero the modified principle is identical to the original principle but the effect of the modification increases with a decreasing value of $\Delta L_0$. 
\[ w_i(f) = \sum_{i}^N w_i(f) \]
\[ w_i'(f) = \begin{cases} \frac{2w_i(f)}{w_i(f)} & \text{if } w_i(f) > 2 \\ w_i(f) & \text{if } w_i(f) \leq 2 \end{cases} \]
\[ \Delta L_0(f) = \sum_{i}^N w_i'(f) \Delta L_i(f) \]
\[ r'(f) = \begin{cases} 0 & \Delta L_0(f) \geq 0 \\ -\Delta L_0(f)/20 & -20 < \Delta L_0(f) < 0 \\ 1 & \Delta L_0(f) \leq -20 \end{cases} \]
\[ \Delta L_i(f) = \Delta L_0(f) \left( 1 - r'(f) + \frac{r'(f)}{\sum w_i'(f)} \right) \]  

5.13 **Sub-Model 4: Terrain with One Screen Having One Edge**

If the terrain has been found to contain one screen with one significant diffracting edge, the terrain effect is calculated by Sub-model 4 described in this section. The description has been divided into two parts. In Section 5.13.1 the base model is described where there is one reflecting surface before the screen and one after the screen. In Section 5.13.2 the general model is described which can have any number of segments before and after the screen.

5.13.1 **Base Model**

In the base model there is one reflecting surface on each side of a wedge-shaped screen as shown in Figure 20. The wedge is defined by the points \( W_1, T_1, \) and \( W_2 \) and reflecting surfaces by \( P_{S1}P_{S2} \) on the source side of the screen and by \( P_{R1}P_{R2} \) on the receiver side. \( S_i \) and \( R_i \) are the image of the source \( S \) and receiver \( R \), respectively. The rays shown in the figure are straight line rays corresponding to a non-refracting atmosphere. For refracting atmospheres the rays will be arcs of circles instead as described in Section 5.5.
In the base model the so-called the image method is used where the sound pressure at the receiver is the sum of coherent contributions from four rays as expressed by Eq. (157). \( p_1 \) is the diffracted sound pressure at the receiver from the source. \( p_2 \) is the diffracted sound pressure at the receiver from the image source, \( p_3 \) is the diffracted sound pressure at the image receiver from the source and \( p_4 \) is the diffracted sound pressure at the image receiver from the image source. The spherical wave reflection coefficients \( Q_1 \) and \( Q_2 \) on the source and receiver side of the screen, respectively, are calculated as if the receiver when calculating \( Q_1 \) or the source when calculating \( Q_2 \) is located at the screen top.

\[
\hat{p} = \hat{p}_1 + \hat{Q}_1 \hat{p}_2 + \hat{Q}_2 \hat{p}_3 + \hat{Q}_1 \hat{Q}_2 \hat{p}_4
\]

(157)

In order to apply the Fresnel-zone interpolation principle described in Section 5.8 the propagation effect is obtained by expressing the sound pressure relative to the free-field sound pressure \( p_0 \) and screen effect and ground effect are separated as shown in Eq.(158). Allthough not indicated all variables in the equation are a function of the frequency. In this equation \( p_{1,ff}/p_0 \) is the effect of the screen in free space and the term in brackets is the effect of the ground in excess of the screen effect. The reason for denoting the diffracted sound pressure from source to receiver \( p_{1,ff} \) in the screen effect part of the equation and \( p_1 \) in ground effect is that different equivalent sound speed profiles are used in the two cases. The linearization used to calculate \( p_{1,ff} \) is independent of the position of the reflecting ground surfaces before and after the screen.

\[
\frac{\hat{p}}{\hat{p}_0} = \frac{\hat{p}_{1,ff}}{\hat{p}_0} \left( 1 + \hat{Q}_1 \frac{\hat{p}_2}{\hat{p}_1} + \hat{Q}_2 \frac{\hat{p}_3}{\hat{p}_1} + \hat{Q}_1 \hat{Q}_2 \frac{\hat{p}_4}{\hat{p}_1} \right)
\]

(158)

If case of reduced efficiency of the ground reflection on the source or receiver side of the screen it may be necessary to modify \( Q_1 \) and \( Q_2 \). In Eq. (159) the modified values are denoted \( Q'_1 \) and \( Q'_2 \) and are obtained by multiplying the original values by a real number \( w_Q \) between 0 and 1. The value 1 indicates a fully efficient ground reflection while 0 indicates
no reflection at all. The calculation of $w_{Q1}$ and $w_{Q2}$ will be described in the general model in Section 5.13.2. As mentioned above the term outside the brackets is the effect of the screen in free space and is denoted $p_{SCR}$ while the term inside the brackets is the effect of the ground and is denoted $p_G$.

$$\frac{\hat{p}}{\hat{p}_0} = \frac{\hat{P}_1,\hat{P}_2, \hat{P}_3, \hat{P}_4}{\hat{P}_0} = \hat{p}_{SCR} \hat{p}_G$$

where

$$\hat{Q}_1' = w_{Q1} \hat{Q}_1$$

and

$$\hat{Q}_2' = w_{Q2} \hat{Q}_2$$

The first step is to determine the variables that have to be calculated to determine the diffracted sound pressures $p_{t1, t2, p_1, p_2, p_3}$ and $p_4$ by the auxiliary function $p_{wedge}$ as shown in Eq. (160). $Z_{5}(f)$ and $Z_{6}(f)$ are the impedance of the source and receiver side wedge face.

$$\hat{p}(f) = p_{wedge}(f, \beta, \theta_s, \theta_R, \tau, \tau_s, \tau_R, \ell, R_S, R_R, \hat{Z}_A(f), \hat{Z}_R(f))$$

To calculate the diffracted sound pressure the input variables in Eq. (160) which are defined in Section 5.7.1 have to be determined. The wedge-shaped screen are defined by the diffracting edge $T_1 = (x_T, y_T)$, the start of the wedge $W_1 = (x_1, z_1)$ closest to source and the end of the wedge $W_2 = (x_2, z_2)$ closest to receiver. The ground segment is defined by the end points $P_{S1} = (x_{S1}, z_{S1})$ and $P_{S2} = (x_{S2}, z_{S2})$ and the ground impedance $Z_{G1}(f)$ on the source side of the screen and by the end points $P_{R1} = (x_{R1}, z_{R1})$ and $P_{R2} = (x_{R2}, z_{R2})$ and the ground impedance $Z_{G2}(f)$ on the receiver side of the screen.

The variables used to calculate $p_{t1, t2}$ is determined according to Eqs. (161) and (162). $d_{base}$ is defined in Eq. (9) and $h_{SCR}$ is determined by Eq. (22). When calculating $p_{t1, t2}$ the equivalent linear sound speed profile is independent of the frequency.

$$\left(x_T', z_T', h_{SCR}\right) = \text{NormLine}(x_{SG1}, z_{SG1}, x_{BG1}, z_{BG1}, x_T, z_T)$$

$$d_{SCR} = \text{Length}(x_{SG1}, z_{SG1}, x_T', z_T')$$

$$d_{SCR2} = d_{base} - d_{SCR}$$

$$\left(\xi_S, c_{0S}, NA\right) = \text{CalcEqSSP}(h_{Sc}, h_{SCR}, z_0, A, B, C)$$

$$\left(\tau_s, R_S, \Delta \theta_s, NA, d_{Sz,S}\right) = \text{DirectRay}(d_{SCR}, h_s, h_{SCR}, \xi_S, c_{0S})$$

$$\left(\xi_R, c_{0R}, NA\right) = \text{CalcEqSSP}(h_{Rc}, h_{SCR}, z_0, A, B, C)$$

$$\left(\tau_R, R_R, \Delta \theta_R, NA, d_{Sz,R}\right) = \text{DirectRay}(d_{SCR2}, h_R, h_{SCR}, \xi_R, c_{0R})$$

$$\tau = \tau_s + \tau_R$$

$$\ell = R_S + R_R$$
The wedge angle \( \beta \) and diffraction angles \( \theta_s \) and \( \theta_R \) can now be determined by Eq. (162) on basis of the wedge coordinates.

\[
\beta_1 = \arctan \left( \frac{z_1 - z_T}{x_T - x_1} \right) + \frac{\pi}{2}
\]
\[
\beta_2 = \arctan \left( \frac{z_2 - z_T}{x_2 - x_T} \right) + \frac{\pi}{2}
\]
\[
\theta_1 = \arctan \left( \frac{z_S - z_T}{x_T - x_S} \right) + \frac{\pi}{2}
\]
\[
\theta_2 = \arctan \left( \frac{z_R - z_T}{x_R - x_T} \right) + \frac{\pi}{2}
\]
\[
\beta = 2\pi - \beta_1 - \beta_2
\]
\[
\theta_S = 2\pi - \theta_1 - \beta_2 - \Delta \theta_S
\]
\[
\theta_R = \theta_2 - \beta_2 + \Delta \theta_R
\]  \hspace{1cm} (162)

The numerical value of the screen effect \( |p_{SCR}| \) is now determined by Eq. (163) where \( p_{1,0}(f) \) is calculated by Eq. (160) using the values of the input variables given in Eqs. (161) and (162). \( R_{SR} \) is the source-receiver distance

\[
|\hat{p}_{SCR}(f)| = |\hat{p}_{1,0}(f)| R_{SR}
\]  \hspace{1cm} (163)

In the calculation of \( p_1 \) to \( p_4 \) the linearization of the sound speed profile used to determine the diffraction angles will still be independent of the frequency in the same way as described for \( p_{1,0} \) but the travel times and travel distances in the ground effect calculation will depend on the frequency as described in Section 5.5.3.

To calculate the sound pressures \( p_1 \) to \( p_4 \) in the ground attenuation part of Eq. (159) the first step is to determine the height \( h'_{S1} \) of the source \( S \) and the height \( h'_{R1} \) of the screen edge \( T_1 \) above the terrain segment on the source side of the screen, and the distances \( d'_1 \) from \( S \) to \( T_1 \), \( d'_{11} \) from \( S \) to the start of the segment, and \( d'_{12} \) from \( S \) to the end of the segment measured along the terrain segment. This is done by the auxiliary function \( SegmentVariables \) described in Section 5.23.15 as shown in Eq. (164). In the same way the height \( h'_{S2} \) of the screen edge \( S \) and the height \( h'_{R2} \) of the receiver \( R \) above the terrain segment on the receiver side of the screen, and the distances \( d'_{2} \) from \( T_1 \) to \( R \), \( d'_{21} \) from \( T \) to the start of the segment, and \( d'_{22} \) from \( T_1 \) to the end of the segment measured along the terrain segment. This is also shown in Eq. (164).

\[
(d'_1, h'_{S1}, h'_{R1}, d'_{11}, d'_{12}) = SegmentVariables(x_S, z_S, x_T, z_T, x_{S1}, z_{S1}, x_{S2}, z_{S2})
\]
\[
(d'_2, h'_{S2}, h'_{R2}, d'_{21}, d'_{22}) = SegmentVariables(x_T, z_T, x_R, z_R, x_{R1}, z_{R1}, x_{R2}, z_{R2})
\]  \hspace{1cm} (164)
When calculating the sound pressure $p_1$ the diffraction angles are the same as used $p_{1,ff}$.

When calculating the sound pressures $p_2$ to $p_4$ diffraction angles $\theta_S$ and $\theta_R$ for the image source and receiver have to be determined as shown in Eq. (165). The angles $\beta, \beta_1$, and $\beta_2$ are the same as calculated in Eq. (162). Due to numerical difficulties in strong upward refraction cases the image point angles $\theta_i$ and $\theta_2$ in Eq. (165) may become larger than corresponding angles of the direct ray defined in Eq. (162). This may lead to erroneous results and in such cases the image point angle shall be set equal to the direct ray angle.

\[
\begin{align*}
(NA, NA, NA, NA, NA, NA, NA, NA) &= \text{ReflectedRay}(d'_i, h'_S1, h'_R1, \xi_S, c_{0S}) \\
(NA, NA, NA, NA, NA, NA, NA, NA) &= \text{ReflectedRay}(d'_i, h'_S2, h'_R2, \xi_R, c_{0R}) \\
(x_{S_i}, \xi_{S_i}) &= \text{ImagePoint}(x_{S1}, \xi_{S1}, x_{S2}, \xi_{S2}, x_S, \xi_S) \\
(x_{R_i}, \xi_{R_i}) &= \text{ImagePoint}(x_{R1}, \xi_{R1}, x_{R2}, \xi_{R2}, x_R, \xi_R)
\end{align*}
\]

\[
\begin{aligned}
\theta_1 &= \arctan\left(\frac{\xi_S - \xi_T}{x_T - x_{S_i}}\right) + \frac{\pi}{2} \\
\theta_2 &= \arctan\left(\frac{\xi_R - \xi_T}{x_R - x_{S_i}}\right) + \frac{\pi}{2} \\
\theta_{S_i} &= 2\pi - \theta_1 - \beta_2 - \Delta\theta_{S_i} \\
\theta_{R_i} &= \theta_2 - \beta_2 + \Delta\theta_{R_i}
\end{aligned}
\] (165)

The travel times and travel distances used to calculate the sound pressures $p_2$ to $p_4$ are based on a frequency dependent linear sound speed profile and will therefore be a function of the frequency.

For the variables of the source side of the screen the modified frequency dependent equivalent linear sound speed profile is determined by the function $\text{CalcEqSSPGround}$ described in Section 5.5.3 as shown in Eq. (166) for average refraction and for upper refraction (indicates by +).

\[
\begin{align*}
(\xi_S(f), c_{0S}(f), \xi'_S, c_{0S}) &= \text{CalcEqSSPGround}(h'_S1, h'_R1, \hat{Z}_{G1}(f), c_0, A, B, C) \\
(\xi'_S(f), c_{0S}(f), NA, NA, NA) &= \text{CalcEqSSPGround}(h'_S1, h'_R1, \hat{Z}_{G1}(f), c_0, A, B, C)
\end{align*}
\] (166)

The ray variables on the source side of the screen are determined for the direct ray and the reflected ray in Eq. (167) for average refraction and upper refraction using the procedures $\text{DirectRay}$ and $\text{ReflectedRay}$ described in Sections 5.5.4 and 5.5.5. NA indicates that a calculated variable is not used. If the calculation by $\text{DirectRay}$ shows that the receiver is in a shadow zone ($\xi_S < 0$ and $d' > 0.95 \, d_{SZ}$) where $d_{SZ}$ is the distance to the shadow zone as defined in Section 5.5.4) calculations by $\text{ReflectedRay}$ are not carried out. The variables $r$, $R$, $\psi_G$, and $\Delta r$ are in the following equations of this section a function of the frequency.
\[
\begin{align*}
\tau_{15}, R_{15}, NA, NA, d_{SZ} & = DirectRay(d'_1, h'_{S1}, h'_{R1}, \xi_s(f), c_{0S}(f)) \\
\tau_{15+}, NA, NA, NA, NA & = DirectRay(d'_1, h'_{S1}, h'_{R1}, \xi_s(f), c_{0S}(f)) \\
\tau_{25}, R_{25}, NA, NA, NA, NA, \psi_{GS}, NA & = \\
& \text{ReflectedRay}(d'_1, h'_{S1}, h'_{R1}, \xi_s(f), c_{0S}(f)) \\
\tau_{25+}, NA, NA, NA, NA, NA, NA & = \\
& \text{ReflectedRay}(d'_1, h'_{S1}, h'_{R1}, \xi_s(f), c_{0S}(f))
\end{align*}
\]

The travel time differences \(\Delta \tau_s\) and \(\Delta \tau_{s+}\) for average and upper refraction are determined by Eq. (168).

\[
\begin{align*}
\Delta \tau_s &= \text{TravelTimeDiff}(\tau_{25}, \tau_{15}) \\
\Delta \tau_{s+} &= \text{TravelTimeDiff}(\tau_{25+}, \tau_{15+})
\end{align*}
\]

The spherical-wave reflection coefficient \(Q_i\) for the terrain reflection on the source side of the screen is calculated by Eq. (169).

\[
\hat{Q}_i = \hat{Q}(f, \tau_{25}, \psi_{GS}, \hat{Z}_{G1})
\]

For the variables of the receiver side of the screen the modified frequency dependent equivalent linear sound speed profile is determined by Eq. (170) for average refraction and for upper refraction (indicates by +).

\[
\begin{align*}
(\xi_R(f), c_{0R}(f), \xi_R, c_{0R}) &= \text{CalcEqSSPGround}(h'_{S2}, h'_{R2}, \hat{Z}_{G2}(f), z_0, A, B, C) \\
(\xi_R, (f), c_{0R}(f), NA, NA, NA) &= \text{CalcEqSSPGrund}(h'_{S2}, h'_{R2}, \hat{Z}_{G2}(f), z_0, A, B, C)
\end{align*}
\]

The ray variables on the receiver side are determined for the direct ray and the reflected ray in Eq. (171) for average and upper refraction using the procedures \textit{DirectRay} and \textit{ReflectedRay} described in Sections 5.5.4 and 5.5.5. NA indicates that a calculated variable is not used. If the calculation by \textit{DirectRay} shows that the receiver is in a shadow zone \((\xi_R < 0\) and \(d'_2 > 0.95 d_{SZ2}\) where \(d_{SZ2}\) is the distance to the shadow zone as defined in Section 5.5.4) calculations by \textit{ReflectedRay} are not carried out. The variables \(\tau, R, \psi_{GS}\), and \(\Delta \tau\) are in the following equations of this section a function of the frequency.
\[
(\tau_{1R}, R_{1R}, NA, NA, d_{sZ, 2}) = \text{DirectRay}(d'_2, h'_{s2}, h'_{R2}, \xi_R(f), c_{0R}(f))
\]
\[
(\tau_{1R}, NA, NA, NA, NA) = \text{DirectRay}(d'_1, h'_{s1}, h'_{R1}, \xi_R, (f), c_{0R}(f))
\]
\[
(\tau_{2R}, R_{2R}, NA, NA, NA, NA, \psi_{GR}, NA) = \text{ReflectedRay}(d'_2, h'_{s2}, h'_{R2}, \xi_R(f), c_{0R}(f))
\]
\[
(\tau_{2R}, NA, NA, NA, NA, NA) = \text{ReflectedRay}(d'_1, h'_{s1}, h'_{R1}, \xi_R, (f), c_{0R}, (f))
\]

(171)

The travel time differences \(\Delta \tau_R\) and \(\Delta \tau_{R+}\) for average and upper refraction are determined by Eq. (172).

\[
\Delta \tau_R = \text{TravelTimeDiff}(\tau_{2R}, \tau_{1R})
\]
\[
\Delta \tau_{R+} = \text{TravelTimeDiff}(\tau_{2R+}, \tau_{1R+})
\]

(172)

The spherical-wave reflection coefficient \(Q_2\) for the terrain reflection on the receiver side of the screen is calculated by Eq. (173).

\[
\hat{Q}_2 = \hat{Q}(f, \tau_{2R}, \psi_{GR}, \hat{Z}_{G2})
\]

(173)

If the size of terrain segment on the source and receiver side is not sufficient large the ground attenuation part \(|p_g|\) of the propagation effect has to be corrected for the limited size of the segments. This is done by calculating the Fresnel-zone weights of each segment \(w_1\) and \(w_2\) as shown in Eq. (174). Subsequently the weights are modified when source or receiver is close to the extension of the segment. The modified weights are denoted \(w'_1\) and \(w'_2\). The modifiers \(r_{S1}, r_{R1}, r_{S2},\) and \(r_{R2}\) are calculated as shown in Eq. (175) and (176). If source or receiver is below the extension of the segment the product of the modifiers becomes 0 which eliminates the problem of the Fresnel-zone weights \(w_1\) and \(w_2\) being undefined in this case. The Fresnel-zone weights are used in the general model described in Section 5.13.2.

\[
(w_1(f), NA, NA, NA, NA) = \text{FresnelZoneW}(d'_1, h'_{s1}, h'_{R1}, d_{11}, d_{12}, 1/16 \lambda, \xi_S, c_{0S})
\]
\[
(w_2(f), NA, NA, NA, NA) = \text{FresnelZoneW}(d'_2, h'_{s2}, h'_{R2}, d_{21}, d_{22}, 1/16 \lambda, \xi_S, c_{0R})
\]
\[
w'_1(f) = w_1(f)r_{S1}r_{R1}
\]
\[
w'_2(f) = w_2(f)r_{S2}r_{R2}
\]

(174)
If the propagation of the four rays in the image model was fully coherent the propagation effect could be determined by Eq. (158) but in order to take into account averaging and incoherent effects as described in Section 0, the coherence coefficient $F_2$, $F_3$, and $F_4$ describing the coherence between ray no. 2, 3, and 4 respectively and the direct ray have to be determined.

The coherence coefficient $F_2$ of ray no. 2 is calculated by Eq. (177) where the coherence coefficients $F_j$, $F_{\Delta r}$, $F_c$, and $F_s$ are calculated as described in Section 0. $\rho_1$ is the transversal separation calculated by Eq. (178), $k_0$ is the wave number at the ground and $r_2$ is the roughness of the source side terrain segment. In case of propagation through a scattering zone $F_s$ is the coherence coefficient calculated as described in Section 5.19. Otherwise $F_s = 1$.

$$F_2(f) = F_j(f, \Delta r_S)F_{\Delta r}(f, \Delta r_S, \Delta r_{S^*})F_c(f, C_r^2, C_\tau^2, t_{\text{mean}}, \bar{C}_S, \rho_1, d_1')F_s(k_0, \psi_{GS}, r_1)F_s(f)$$ (177)
\[ \rho_1 = \frac{2h_s' h_{s1}}{h_s' + h_{s1}} \] (178)

The coherence coefficient \( F_3 \) of ray no. 3 is calculated by Eq. (179) where the coherence coefficients \( F_j, F_{\Delta t}, F_c, \) and \( F_r \) are calculated as described in Section 0. \( \rho_2 \) is the transversal separation calculated by Eq. (180), \( k_0 \) is the wave number at the ground and \( r_2 \) is the roughness of the receiver side terrain segment.

\[ F_3(f) = F_j(f, \Delta \tau_R) F_{\Delta t} \left( f, \Delta \tau_R \Delta \tau_{R*} \right) F_c \left( f, C_v^2, t_{\text{mean}}, \bar{c}_R, \rho_2, d_2' \right) F_r \left( k_0, \psi_{GR}, r_2 \right) F_s(f) \] (179)

\[ \rho_2 = \frac{2h_{s2}' h_{r2}}{h_{r2}' + h_{r2}} \] (180)

The coherence coefficient \( F_4 \) of ray no. 4 is calculated by Eq. (181).

\[ F_4(f) = F_j \left( f, \Delta \tau_S + \Delta \tau_R \right) F_{\Delta t} \left( f, \Delta \tau_S + \Delta \tau_R \Delta \tau_{S*} + \Delta \tau_{R*} \right) F_c \left( f, C_v^2, C_T^2, t_{\text{mean}}, \bar{c}_S, \rho_1, d_1' \right) F_r \left( k_0, \psi_{GS}, r_1 \right) F_s(f) \] (181)

Now the propagation effect can be determined by Eq. (182) if shadow zone effects occur neither on the source side of the screen nor on the receiver side.

\[ |\hat{p}_G| = \left[ 1 + F_2 \frac{w_{Q1} \hat{Q}_1 \hat{p}_2}{\hat{p}_1} + F_3 \frac{w_{Q2} \hat{Q}_2 \hat{p}_3}{\hat{p}_1} + F_4 \frac{w_{Q1} \hat{Q}_1 w_{Q2} \hat{Q}_2 \hat{p}_4}{\hat{p}_1} \right] + \left( 1 - F_2 \right) \frac{w_{Q1} \hat{p}_2}{\hat{p}_1} \left| \hat{p}_1 \right|^2 + \left( 1 - F_3 \right) \frac{w_{Q2} \hat{p}_3}{\hat{p}_1} \left| \hat{p}_1 \right|^2 + \left( 1 - F_4 \right) \frac{w_{Q1} w_{Q2} \hat{p}_4}{\hat{p}_1} \left| \hat{p}_1 \right|^2 \] (182)

The incoherent reflection coefficients \( \mathcal{R}_j \) and \( \mathcal{R}_2 \) in Eq. (182) are determined by Eq. (183).

\[ \mathcal{R}_1 = \mathfrak{Re} \left( f, \hat{Z}_{G1} \right) \] \[ \mathcal{R}_2 = \mathfrak{Re} \left( f, \hat{Z}_{G2} \right) \] (183)

If \( d' > 0.95d_{SZ,1} \) and \( d' \leq 0.95d_{SZ,2} \) shadow zone effects will occur on the source side of the screen and \( |\hat{p}_G| \) has to be calculated by Eq. (184) where \( |\hat{p}_G|^{\text{Eq.182}} \) indicates the value calculated by Eq. (182) with modified values of \( Q_1, p_2 \) and \( p_4 \).
\[
\left| \tilde{p}_G \right| = 10^{\Delta L_{SZ,1}(f)/20} \left| p_G \right|^{\text{Eq.182}}
\]

where

\[
\Delta L_{SZ,1}(f) = \text{ShadowZoneShielding} \left( f, d_1', h_s, h_{r1}, \xi, c_{0s}, d_{sz,1} \right)
\]

\[
\hat{Q}(f) = \tilde{Q}(f, \tau_{1s}, 0, \tilde{Z}_{G1}(f))
\]

\[
\hat{p}_2 = \hat{p}_1
\]

\[
\hat{p}_4 = \hat{p}_3
\]

If \( d' > 0.95d_{sz,2} \) and \( d' \leq 0.95d_{sz,1} \) shadow zone effects will occur on the receiver side of the screen and \( |p_G| \) has to be calculated by Eq. (185) where \( |p_G|^{\text{Eq.182}} \) indicates the value calculated by Eq. (182) with modified values of \( Q_2, p_3 \) and \( p_4 \).

\[
\left| \tilde{p}_G \right| = 10^{\Delta L_{SZ,2}(f)/20} \left| p_G \right|^{\text{Eq.182}}
\]

where

\[
\Delta L_{SZ,2}(f) = \text{ShadowZoneShielding} \left( f, d_2', h_s, h_{r2}, \xi, c_{0s}, d_{sz,2} \right)
\]

\[
\hat{Q}_2(f) = \tilde{Q}_2(f, \tau_{1r}, 0, \tilde{Z}_{G2}(f))
\]

\[
\hat{p}_3 = \hat{p}_1
\]

\[
\hat{p}_4 = \hat{p}_2
\]

If \( d' > 0.95d_{sz,1} \) and \( d' > 0.95d_{sz,2} \) shadow zone effects will occur on both sides of the screen and \( |p_G| \) has to be calculated by Eq. (186) where \( |p_G|^{\text{Eq.182}} \) indicates the value calculated by Eq. (182) with modified values of \( Q_1, Q_2, p_2, p_3, \) and \( p_4 \).

\[
\left| \tilde{p}_G \right| = 10^{\Delta L_{SZ,1}(f)/20} \left| \tilde{p}_G \right|^{\text{Eq.182}}
\]

where

\[
\Delta L_{SZ,1}(f) = \text{ShadowZoneShielding} \left( f, d_1', h_s, h_{r1}, \xi, c_{0s}, d_{sz,1} \right)
\]

\[
\Delta L_{SZ,2}(f) = \text{ShadowZoneShielding} \left( f, d_2', h_s, h_{r2}, \xi, c_{0s}, d_{sz,2} \right)
\]

\[
\hat{Q}(f) = \tilde{Q}(f, \tau_{1s}, 0, \tilde{Z}_{G1}(f))
\]

\[
\hat{Q}_2(f) = \tilde{Q}_2(f, \tau_{1r}, 0, \tilde{Z}_{G2}(f))
\]

\[
\hat{p}_4 = \hat{p}_1
\]

\[
\hat{p}_3 = \hat{p}_1
\]

\[
\hat{p}_2 = \hat{p}_1
\]
5.13.2 General Model

If the terrain has been found to contain one screen with one significant diffracting edge, the terrain effect is calculated by Sub-model 4 described in this section. An example of such a terrain is shown in Figure 21 where the two segments denoted 4 and 5 form a wedge-shaped screen. The remaining five segments will be considered reflecting surfaces. Segments 1–3 will form the surface on the source side of the screen while segments 6–7 form the surface on the receiver side.

![Figure 21](image)

*Figure 21*
Example of a segmented terrain with one screen having one diffracting edge

At this point it is assumed that the screen part of the terrain profile has already been identified and therefore that the number of segments before and after the screen which are considered reflecting segments are known. If the part of the input terrain forming the screen shape contains more than three ground points the screen shape is reduced to three points as described in Section 5.21.

The screen is defined by the following point numbers in the terrain profile (numbered 1 to \(N_{ts}+1\) where \(N_{ts}\) is the number of segments in the terrain profile).

- \(iSCR,1\) terrain point number closest to the source
- \(iSCR,2\) terrain point number closest to the receiver
- \(iSCR,T\) terrain point number of the diffracting edge
Therefore, the line segment representing the wedge face closest to the source has the end coordinates \( W_1 = (x_{iSCR,1}, z_{iSCR,1}) \) and \( T_1 = (x_{iSCR,T,1}, z_{iSCR,T,1}) \) while the line segment representing the wedge face closest to the receiver has the end coordinates \( W_1 = (x_{iSCR,2}, z_{iSCR,2}) \) and \( T_1 = (x_{iSCR,T,2}, z_{iSCR,T,2}) \). Possible terrain points between point no. \( iSCR,1 \) and \( iSCR,T \) and between point no. \( iSCR,2 \) and \( iSCR,T \) are ignored. In this case the flow resistivity \( \sigma_{iSCR,T-1} \) is used as representative to the source side wedge face and \( \sigma_{iSCR,T} \) is used as representative to the receiver side wedge face. In the example in Figure 21 \( iSCR,I = 4 \), \( iSCR,2 = 6 \) and \( iSCR,S = 5 \).

The number of reflecting segments before the screen will therefore be \( iSCR,1-1 \) numbered from \( N_{S1} = 1 \) to \( N_{S2} = iSCR,1 - 1 \) while the number of reflecting segments after the screen will be \( N_{R1} + 1 - iSCR,2 \) numbered from \( N_{R1} = iSCR,2 \) to \( N_{R2} = N_{R} \).

The base model will now used for all combinations of segments of the source side (\( i_1 = N_{S1} \) to \( N_{S2} \)) and on the receiver side (\( i_2 = N_{R1} \) to \( N_{R2} \)). For each case of \( i_1 \) and \( i_2 \) the coordinates to use in the base model are:

- \( T_1 = (x_T, z_T) = (x_{iSCR,T}, z_{iSCR,T}) \)
- \( W_1 = (x_1, z_1) = (x_{iSCR,1}, z_{iSCR,1}) \)
- \( W_2 = (x_2, z_2) = (x_{iSCR,2}, z_{iSCR,2}) \)
- \( Z_S = Z_{iSCR,T-1} \)
- \( Z_R = Z_{iSCR,T} \)
- \( P_{S1} = (x_{S1}, z_{S1}) = (x_{i1}, z_{i1}) \)
- \( P_{S2} = (x_{S2}, z_{S2}) = (x_{i1+1}, z_{i1+1}) \)
- \( Z_{G1} = z_{i1} \)
- \( w''_1(f) = w''_{i1}(f) \)
- \( P_{R1} = (x_{R1}, z_{R1}) = (x_{i2}, z_{i2}) \)
- \( P_{R2} = (x_{R2}, z_{R2}) = (x_{i2+1}, z_{i2+1}) \)
- \( Z_{G2} = z_{i2} \)
- \( w''_2(f) = w''_{i2}(f) \)

The base model is used to calculate the screen effect \(|p_{SCR}|\) and the ground effect \(|p_G|\). The former will be identical for all combinations of terrain segment and has to be calculated only once while the latter will vary for each combination of terrain terrain segments and
will be denoted $|p_{G_{i1,i2}}|$ for segment $i1$ on the source side of the screen and $i2$ on the receiver side.

Based on the sum of Fresnel-zone weights $w''_{i1}(f) = w''_{i2}(f)$ and $w''_{i2}(f) = w''_{i2}(f)$ on each side of the screen the Fresnel-zone weights are normalized as shown in Eq. (187) and the weights $w_{Q1}$ and $w_{Q2}$ used the base model are determined.

$$w_{i1}^r(f) = \sum_{i=N_{i1}}^{N_{i2}} w_{i1}^n(f)$$

$$w_{i2}^r(f) = \sum_{i=N_{i1}}^{N_{i2}} w_{i2}^n(f)$$

$$\Delta w_{i1} = \begin{cases} w_{i1}^r(f) - 1 & \text{if } w_{i1}^r(f) > 1 \\ 0 & \text{if } w_{i1}^r(f) \leq 1 \end{cases}$$

$$\Delta w_{i2} = \begin{cases} w_{i2}^r(f) - 1 & \text{if } w_{i2}^r(f) > 1 \\ 0 & \text{if } w_{i2}^r(f) \leq 1 \end{cases}$$

$$\Delta w_i(f) = \Delta w_{i1}(f) + \Delta w_{i2}(f)$$

$$\frac{w_i^n(f)(\Delta w_i(f) + 1)}{w_i^r(f)} \text{ if } w_i(f) > 1$$

$$\frac{w_i^n(f)}{w_i^r(f)} \text{ if } 0 < w_i(f) \leq 1$$

$$0 \text{ if } w_i(f) = 0$$

$$w_{i2}^r(f) = \begin{cases} w_{i2}^n(f) \frac{\Delta w_{i2}(f) + 1}{\Delta w_i(f)} & \text{if } w_{i2}^r(f) > 1 \\ 0 & \text{if } w_{i2}^r(f) = 0 \end{cases}$$

$$w_{Q1}(f) = \begin{cases} 1 & \text{if } w_{i1}(f) \geq 1 \\ w_{i1}^n(f) & \text{if } w_{i1}(f) < 1 \end{cases}$$

$$w_{Q2}(f) = \begin{cases} 1 & \text{if } w_{i2}(f) \geq 1 \\ w_{i2}^n(f) & \text{if } w_{i2}(f) < 1 \end{cases}$$

Finally the sound pressure level $\Delta L_d$ of Sub-model 4 for a terrain with one screen having one edge is calculated according to Eq. (188).
\[ \Delta L_4 = 20 \log \left( \hat{p}_{SCR}(f) \prod_{i=1}^{N_{s1}} \prod_{j=1}^{N_{s2}} \hat{p}_{G,i\cdot j2}(f) \hat{p}_{G,i\cdot j2}(f) \right) \] (188)

5.14 Sub-Model 5: Terrain with One Screen Having Two Edges

If the terrain has been found to contain one screen with two significant diffracting edges, the terrain effect is calculated by Sub-model 5 described in this section. The description has been divided into two parts. In Section 5.14.1 the base model is described where there is one reflecting surface before the screen and one after the screen. In Section 5.14.2 the general model is described which can have any number of segments before and after the screen.

5.14.1 Base Model

In the base model there is one reflecting surface on each side of a wedge-shaped screen as shown in Figure 22. The wedge is defined by the points \( W_1, T_1, T_2, \) and \( W_2 \) and reflecting surfaces by \( P_{S1}P_{R1} \) on the source side of the screen and by \( P_{S2}P_{R2} \) on the receiver side. \( S_i \) and \( R_i \) are the image of the source \( S \) and receiver \( R \), respectively. \( T_1 \) and \( T_2 \) are the two diffracting edges. The rays shown in the figure are straight line rays corresponding to a non-refracting atmosphere. For refracting atmospheres the rays will be arcs of circles instead as described in Section 5.5.

\[ \text{Figure 22} \]
\[ \text{Definition of geometry for the base model.} \]

In the base model the image method is used where the sound pressure at the receiver is the sum of coherent contributions from four rays as expressed by Eq. (189). \( p_1 \) is the diffracted sound pressure at the receiver from the source. \( p_2 \) is the diffracted sound pressure at the receiver from the image source. \( p_3 \) is the diffracted sound pressure at the image receiver.
from the source and $p_1$ is the diffracted sound pressure at the image receiver from the image source. The spherical wave reflection coefficients $Q_1$ and $Q_2$ on the source and receiver side of the screen, respectively, are calculated as if the receiver is located at $T_1$ when calculating $Q_1$ or the source is located at $T_2$ when calculating $Q_2$.

$$\hat{p} = \hat{p}_1 + \hat{Q}_1\hat{p}_2 + \hat{Q}_2\hat{p}_3 + \hat{Q}_1\hat{Q}_2\hat{p}_4$$  \hspace{1cm} (189)

In order to apply the Fresnel-zone interpolation principle described in Section 5.8 the propagation effect is obtained by expressing the sound pressure relative to the free-field sound pressure $p_0$ and screen effect and ground effect are separated as shown in Eq.(190). Although not indicated all variables in the equation is a function of the frequency. In this equation $p_{1,ff}/p_0$ is the effect of the screen in free space and the term in brackets is the effect of the ground in excess of the screen effect. The reason for denoting the diffracted sound pressure from source to receiver $p_{1,ff}$ in the screen effect part of the equation and $p_1$ in ground effect is that different equivalent sound speed profiles are used in the two cases. The linearization used to calculate $p_{1,ff}$ is independent of the position of the reflecting ground surfaces before and after the screen.

$$\frac{\hat{p}}{\hat{p}_0} = \frac{\hat{p}_{1,ff}}{\hat{p}_0} \left(1 + \hat{Q}_1\frac{\hat{p}_2}{\hat{p}_1} + \hat{Q}_2\frac{\hat{p}_3}{\hat{p}_1} + \hat{Q}_1\hat{Q}_2\frac{\hat{p}_4}{\hat{p}_1}\right)$$  \hspace{1cm} (190)

If case of reduced efficiency of the ground reflection on the source or receiver side of the screen it may be necessary to modify $Q_1$ and $Q_2$. In Eq. (191) the modified values are denoted $Q'_1$ and $Q'_2$ and are obtained by multiplying the original values by a real number $w_Q$ between 0 and 1. The value 1 indicates a fully efficient ground reflection while 0 indicates no reflection at all. The calculation of $w_{Q1}$ and $w_{Q2}$ will be described in the general model in Section 5.14.2. As mentioned above the term outside the brackets is the effect of the screen in free space and is denoted $p_{SCR}$ while the term inside the brackets is the effect of the ground and is denoted $p_G$.

$$\frac{\hat{p}}{\hat{p}_0} = \frac{\hat{p}_{1,ff}}{\hat{p}_0} \left(1 + \hat{Q}'_1\frac{\hat{p}_2}{\hat{p}_1} + \hat{Q}'_2\frac{\hat{p}_3}{\hat{p}_1} + \hat{Q}_1\hat{Q}_2\frac{\hat{p}_4}{\hat{p}_1}\right) = \hat{p}_{SCR}\hat{p}_G$$

where 

$$\hat{Q}'_1 = w_{Q1}\hat{Q}_1$$

and 

$$\hat{Q}'_2 = w_{Q2}\hat{Q}_2$$  \hspace{1cm} (191)

The first step is to determine the variables that have to be used to calculate the diffracted sound pressures $p_{1,ff}$, $p_1$, $p_2$, $p_3$ and $p_4$ by the auxiliary function $p_{2edge}$ as shown in Eq. (192). $Z_S(f)$ and $Z_R(f)$ are the impedance of the source and receiver side wedge face.
\[ \hat{p}(f) = p2edge\{f, \beta_1, \theta_{1S}, \theta_{1R}, \beta_2, \theta_{2S}, \theta_{2R}, \tau_s, \tau_M, R_s, R_M, R_c, \hat{Z}_S(f), \hat{Z}_R(f)\} \]  \tag{192}

To calculate the diffracted sound pressure the input variables in Eq. (192) which are defined in Section 5.7.4 have to be determined. The screen is defined by the diffracting edge \( T_1 = (x_{T1}, x_{T1}) \) and \( T_2 = (x_{T1}, x_{T1}) \), the start of the wedge \( W_1 = (x_{1S}, z_{1S}) \) closest to source and the end of the wedge \( W_2 = (x_{2S}, z_{2S}) \) closest to receiver. The ground segment is defined by the end points \( P_{S1} = (x_{S1}, z_{S1}) \) and \( P_{S2} = (x_{S2}, z_{S2}) \) and the ground impedance \( Z_{G1}(f) \) on the source side of the screen and by the end points \( P_{R1} = (x_{R1}, z_{R1}) \) and \( P_{R2} = (x_{R2}, z_{R2}) \) and the ground impedance \( Z_{G2}(f) \) on the receiver side of the screen.

The variables used to calculate \( p_{1,ff} \) is determined according to Eqs. (193) through (195). \( d_{\text{base}} \) is defined in Eq. (9) and \( h''_{SCR} \) is by determined by Eq. (22). When calculating \( p_{1,ff} \) the equivalent linear sound speed profile is independent of the frequency.

\[
\begin{align*}
(x'_{T1}, z'_{T1}, h'_{SCR}) &= \text{NormLine}(x_{SGv}, z_{SGv}, x_{RGv}, z_{RGv}, x_{T1}, z_{T1}) \\
(x'_{T2}, z'_{T2}, h'_{SCR}) &= \text{NormLine}(x_{SGv}, z_{SGv}, x_{RGv}, z_{RGv}, x_{T2}, z_{T2}) \\
d_{SCR1} &= \text{Length}(x_{SGv}, z_{SGv}, x'_{T1}, z'_{T1}) \\
d_{SCR2} &= \text{Length}(x_{SGv}, z_{SGv}, x'_{T2}, z'_{T2}) - d_{SCR1} \\
d_{SCR3} &= d_{\text{base}} - d_{SCR2} - d_{SCR1} \\
(\xi_s, c_{0S}, NA) &= \text{CalcEqSSP}(h_{sv}, h''_{SCR}, z_0, A, B, C) \\
(\tau_S, R_S, \Delta \theta_S, NA, d_{S,s,S}) &= \text{DirectRay}(d_{_SCR1}, h_S, h''_{SCR}, \xi_S, c_{0S}) \\
(\xi_M, c_{0M}, NA) &= \text{CalcEqSSP}(h''_{SCR}, h''_{SCR}, z_0, A, B, C) \\
(\tau_M, R_M, \Delta \theta_M, NA, NA) &= \text{DirectRay}(d_{SCR2}, h''_{SCR}, h''_{SCR}, \xi_M, c_{0M}) \\
(\xi_R, c_{0R}, NA) &= \text{CalcEqSSP}(h_{rv}, h''_{SCR}, z_0, A, B, C) \\
(\tau_R, R_R, \Delta \theta_R, NA, d_{S,S,R}) &= \text{DirectRay}(d_{SCR3}, h_R, h''_{SCR}, \xi_R, c_{0R})
\end{align*}
\] \tag{193}

The wedge angle \( \beta_1 \) and diffraction angles \( \theta_{1S} \) and \( \theta_{1R} \) of the first wedge (T1) can now be determined by Eq. (194) on basis of the screen coordinates.
\[ \beta_{11} = \arctan \left( \frac{z_1 - z_{T1}}{x_{T1} - x_1} \right) + \frac{\pi}{2} \]

\[ \beta_{12} = \arctan \left( \frac{z_{T2} - z_{T1}}{x_{T2} - x_{T1}} \right) + \frac{\pi}{2} \]

\[ \theta_{11} = \arctan \left( \frac{z_s - z_{T1}}{x_{T1} - x_s} \right) + \frac{\pi}{2} \]

\[ \theta_{12} = \max \left( \arctan \left( \frac{z_{T2} - z_{T1}}{x_{T2} - x_{T1}} \right), \arctan \left( \frac{z_R - z_{T1}}{x_{R} - x_{T1}} \right), \arctan \left( \frac{z_{T2} - z_{T1}}{x_{T2} - x_{T1}} \right) + \frac{\pi}{2} \right) \]

\[ \beta_1 = 2\pi - \beta_{11} - \beta_{12} \]

\[ \theta_{1S} = 2\pi - \theta_{11} - \theta_{12} - \Delta \theta_S \]

\[ \theta_{1R} = \theta_{12} - \beta_{12} + \Delta \theta_M \]

The wedge angle \( \beta_2 \) and diffraction angles \( \theta_{2S} \) and \( \theta_{2R} \) of the second wedge \( (T_2) \) can be determined by Eq. (195) on basis of the screen coordinates.

\[ \beta_{21} = \arctan \left( \frac{z_{T1} - z_{T2}}{x_{T2} - x_{T1}} \right) + \frac{\pi}{2} \]

\[ \beta_{22} = \arctan \left( \frac{z_2 - z_{T2}}{x_2 - x_{T2}} \right) + \frac{\pi}{2} \]

\[ \theta_{21} = \max \left( \arctan \left( \frac{z_{T1} - z_{T2}}{x_{T2} - x_{T1}} \right), \arctan \left( \frac{z_s - z_{T2}}{x_{T2} - x_s} \right) \right) + \frac{\pi}{2} \]

\[ \theta_{22} = \arctan \left( \frac{z_{R} - z_{T2}}{x_{R} - x_{T2}} \right) + \frac{\pi}{2} \]

\[ \beta_2 = 2\pi - \beta_{21} - \beta_{22} \]

\[ \theta_{2S} = 2\pi - \theta_{21} - \beta_{22} - \Delta \theta_M \]

\[ \theta_{2R} = \theta_{22} - \beta_{22} + \Delta \theta_R \]

The numerical value of the screen effect \( |p_{SCR}| \) is now determined by Eq. (196) where \( p_{1...}(f) \) is calculated by Eq. (192) using the values of the input variables given in Eqs. (193) through (195). \( R_{SR} \) is the source-receiver distance.

\[ |\hat{P}_{SCR}(f)| = |\hat{P}_{1...}(f)| R_{SR} \]  

(196)

In the calculation of \( p_1 \) to \( p_4 \) the linearization of the sound speed profile used to determine the diffraction angles will still be independent of the frequency in the same way as de-
scribed for \( p_{1,fr} \) but the travel times and travel distances in the ground effect calculation will depend on the frequency as described in Section 5.5.3.

To calculate the sound pressures \( p_1 \) to \( p_4 \) in the ground attenuation part of Eq. (191) the first step is to determine the height \( h'_{S1} \) of the source \( S \) and the height \( h'_{R1} \) of the screen edge \( T \) above the terrain segment on the source side of the screen, and the distances \( d'_{11} \) from \( S \) to \( T \), \( d'_{12} \) from \( S \) to the start of the segment, and \( d'_{22} \) from \( S \) to the end of the segment measured along the terrain segment. This is done by the auxiliary function \( \text{SegmentVariables} \) described in Section 5.23.15 as shown in Eq. (197). In the same way the height \( h'_{S2} \) of the screen edge \( S \) and the height \( h'_{R2} \) of the receiver \( R \) above the terrain segment on the receiver side of the screen, and the distances \( d'_{2} \) from \( T \) to \( R \), \( d'_{21} \) from \( T \) to the start of the segment, and \( d'_{22} \) from \( T \) to the end of the segment measured along the terrain segment. This is also shown in Eq. (197).

\[
(d'_{11}, h'_{S1}, h'_{R1}, d'_{12}, d'_{22}) = \text{SegmentVariables}(x_S, z_S, x_{T1}, z_{T1}, x_{S1}, z_{S1}, x_{S2}, z_{S2})
\]
\[
(d'_{2}, h'_{S2}, h'_{R2}, d'_{21}, d'_{22}) = \text{SegmentVariables}(x_{T2}, z_{T2}, x_R, z_R, x_{R1}, z_{R1}, x_{R2}, z_{R2})
\]  

When calculating the sound pressure \( p_1 \) the diffraction angles are the same as used \( p_{1,fr} \).
When calculating the sound pressures \( p_2 \) to \( p_4 \) diffraction angles \( \theta_{Si} \) and \( \theta_{Ri} \) for the image source and receiver have to be determined as shown in Eq. (198). The \( \beta \) angles are the same as calculated in Eqs. (194) and (195). Due to numerical difficulties in strong upward refraction cases the image point angles \( \theta_{1j} \) and \( \theta_{2j} \) in Eq. (198) may become larger than corresponding angles of the direct ray defined in Eqs. (194) and (195). This may lead to erroneous results and in such cases the image point angle shall be set equal to the direct ray angle.

\[
\begin{align*}
(NA, NA, NA, NA, NA, \Delta \theta_{Si}, NA, NA) &= \text{ReflectedRay}(d'_{11}, h'_{S1}, h'_{R1}, z_S, c_{0S}) \\
(NA, NA, NA, NA, \Delta \theta_{Ri}, NA, NA, NA) &= \text{ReflectedRay}(d'_{2}, h'_{S2}, h'_{R2}, z_R, c_{0R}) \\
(x_{Si}, z_{Si}) &= \text{ImagePoint}(x_{S1}, z_{S1}, x_{S2}, z_{S2}, x_S, z_S) \\
(x_{Ri}, z_{Ri}) &= \text{ImagePoint}(x_{R1}, z_{R1}, x_{R2}, z_{R2}, x_R, z_R) \\
\theta_{11} &= \arctan\left(\frac{z_{S1} - z_{T1}}{x_{T1} - x_{S1}}\right) + \frac{\pi}{2} \\
\theta_{22} &= \arctan\left(\frac{z_{Ri} - z_{T2}}{x_{R2} - x_{T2}}\right) + \frac{\pi}{2} \\
\theta_{1Si} &= 2\pi - \theta_{11} - \beta_{12} - \Delta \theta_{Si} \\
\theta_{2Ri} &= \theta_{22} - \beta_{22} + \Delta \theta_{Ri}
\end{align*}
\]  

The travel times and travel distances used to calculate the sound pressures \( p_2 \) to \( p_4 \) are based on a frequency dependent linear sound speed profile and will therefore be a function of the frequency.
For the variables of the source side of the screen the modified frequency dependent equivalent linear sound speed profile is determined by the function $CalcEqSSPGround$ described in Section 5.5.3 as shown in Eq. (199) for average refraction and for upper refraction (indicates by $+$).

\[
(\xi_s(f), c_{0S}(f), \xi_s, c_{0S}) = CalcEqSSPGround(h_{S1}', h_{R1}', \hat{Z}_{G1}(f), z_0, A, B, C)
\]

\[
(\xi_{S+}(f), c_{0S+}(f), NA, NA, NA) = CalcEqSSPGround(h_{S1}', h_{R1}', \hat{Z}_{G1}(f), z_0, A_+, B_+, C)
\]  

The ray variables on the source side of the screen are determined for the direct ray and the reflected ray in Eq. (200) for average refraction and upper refraction using the procedures $DirectRay$ and $ReflectedRay$ described in Sections 5.5.4 and 5.5.5. NA indicates that a calculated variable is not used. If the calculation by $DirectRay$ shows that the receiver is in a shadow zone ($\xi_s < 0$ and $d'_1 > 0.95d_{SZ}$ where $d_{SZ}$ is the distance to the shadow zone as defined in Section 5.5.4) calculations by $ReflectedRay$ are not carried out. The variables $\tau$, $R$, $\psi$, and $\Delta \tau$ are in the following equations of this section a function of the frequency.

\[
(\tau_{1S}, R_{1S}, NA, NA, d_{SZ}) = DirectRay(d'_1, h_{S1}', h_{R1}', \xi_s(f), c_{0S}(f))
\]

\[
(\tau_{1S+}, NA, NA, NA, NA) = DirectRay(d'_1, h_{S1}', h_{R1}', \xi_{S+}(f), c_{0S+}(f))
\]

\[
(\tau_{2S}, R_{2S}, NA, NA, NA, \psi_{GS}, NA) =\]

\[
ReflectedRay(d'_1, h_{S1}', h_{R1}', \xi_s(f), c_{0S}(f)
\]

\[
(\tau_{2S+}, NA, NA, NA, NA, NA, NA) =\]

\[
ReflectedRay(d'_1, h_{S1}', h_{R1}', \xi_{S+}(f), c_{0S+}(f))
\]

The travel time differences $\Delta \tau_S$ and $\Delta \tau_{S+}$ for average and upper refraction are determined by Eq. (201).

\[
\Delta \tau_S = TravelTimeDiff(\tau_{2S}, \tau_{1S})
\]

\[
\Delta \tau_{S+} = TravelTimeDiff(\tau_{2S+}, \tau_{1S+})
\]

The spherical-wave reflection coefficient $Q_1$ for the terrain reflection on the source side of the screen is calculated by Eq. (202).

\[
\hat{Q}_1 = \hat{Q}(f, \tau_{2S}, \psi_{GS}, \hat{Z}_{G1})
\]

For the variables of the receiver side of the screen the modified frequency dependent equivalent linear sound speed profile is determined by Eq. (203) for average refraction and for upper refraction (indicates by $+$).
\[
(\xi_R(f),c_{0R}(f),\xi_R, c_{0R}) = \text{CalcEqSSPG round}(h_{S2}', h_{R2}', \tilde{Z}_{G2}(f), z_0, A, B, C)
\]
\[
(\xi_R, f, c_{0R}, f, NA, NA, NA) = \text{CalcEqSSPG round}(h_{S2}', h_{R2}', \tilde{Z}_{G2}(f), z_0, A, B, C)
\]

The ray variables on the receiver side are determined for the direct ray and the reflected ray in Eq. (204) for average and upper refraction using the procedures \text{DirectRay} and \text{ReflectedRay} described in Sections 5.5.4 and 5.5.5. NA indicates that a calculated variable is not used. If the calculation by \text{DirectRay} shows that the receiver is in a shadow zone \((\xi_R < 0)\) and \(d'_2 > 0.95 \, d_{SZ2}\) where \(d_{SZ2}\) is the distance to the shadow zone as defined in Section 5.5.4) calculations by \text{ReflectedRay} are not carried out. The variables \(\tau, R, \psi_G,\) and \(\Delta \tau\) are in the following equations of this section a function of the frequency.

\[
(\tau_{1R}, R_{1R}, NA, NA, d_{SZ2}) = \text{DirectRay}(d'_2, h_{S2}', h_{R2}', \xi_R, f, c_{0R}(f))
\]
\[
(\tau_{1R}, NA, NA, NA, NA, NA) = \text{DirectRay}(d'_2, h_{S2}', h_{R2}', \xi_R, f, c_{0R}(f))
\]
\[
(\tau_{2R}, R_{2R}, NA, NA, NA, NA, \psi_{GR}, NA) = \text{ReflectedRay}(d'_2, h_{S2}', h_{R2}', \xi_R, f, c_{0R}(f))
\]
\[
(\tau_{2R}, NA, NA, NA, NA, NA, NA, NA) = \text{ReflectedRay}(d'_2, h_{S2}', h_{R2}', \xi_R, f, c_{0R}(f))
\]

The travel time differences \(\Delta \tau_R\) and \(\Delta \tau_{R+}\) for average and upper refraction are determined by Eq. (205).

\[
\Delta \tau_R = \text{TravelTimeDiff} (\tau_{2R}, \tau_{1R})
\]
\[
\Delta \tau_{R+} = \text{TravelTimeDiff} (\tau_{2R}, \tau_{1R+})
\]

The spherical-wave reflection coefficient \(Q_2\) for the terrain reflection on the receiver side of the screen is calculated by Eq. (206).

\[
\hat{Q}_2 = \hat{Q}(f, \tau_{2R}, \psi_{GR}, \tilde{Z}_{G2})
\]

If the size of terrain segment on the source and receiver side is not sufficient large the ground attenuation part \(|p_G|\) of the propagation effect has to be corrected for the limited size of the segments. This is done by calculating the Fresnel-zone weights of each segment \(w_1\) and \(w_2\) as shown in Eq. (207). Subsequently the weights are modified when source or receiver is close to the extension of the segment. The modified weights are denoted \(w''_1\) and \(w''_2\). The modifiers \(r_{S1}, r_{R1}, r_{S2},\) and \(r_{R2}\) are calculated as shown in Eq. (208) and (209). If source or receiver is below the extension of the segment the product of the modifiers becomes 0 which eliminates the problem of the Fresnel-zone weights \(w_i\) and \(w_j\) being undefined in this case. The Fresnel-zone weights are used in the general model described in Section 5.13.2.
\[
(w_1(f), NA, NA, NA, NA) = \text{FresnelZoneW}(d'_1, h'_s, h'_r, d_{11}, d_{12}, 1/16 \lambda, \xi_s, c_{0S})
\]
\[
(w_2(f), NA, NA, NA, NA) = \text{FresnelZoneW}(d'_2, h'_s, h'_r, d_{21}, d_{22}, 1/16 \lambda, \xi_s, c_{0R})
\]
\[
w_1^*(f) = w_1(f) r_{S1} r_{R1}
\]
\[
w_2^*(f) = w_2(f) r_{S2} r_{R2}
\]
\[
h_{max,1} = \text{Min}(0.0005(x_T - x_S), 0.2)
\]
\[
h_1^* = \text{Min}(h_s, h_{max,1})
\]
\[
r_{S1} = \begin{cases} 
1 & h'_s \geq h_1^* \\
h'_s & 0 < h'_s < h_1^* \\
0 & h'_s \leq 0 
\end{cases}
\]
\[
r_{R1} = \begin{cases} 
1 & h'_r \geq h_{max,1} \\
h'_r & 0 < h'_r < h_{max,1} \\
0 & h'_r \leq 0 
\end{cases}
\]
\[
h_{max,2} = \text{Min}(0.0005(x_R - x_T), 0.2)
\]
\[
h_2^* = \text{Min}(h_r, h_{max,2})
\]
\[
r_{R2} = \begin{cases} 
1 & h'_r \geq h_2^* \\
h'_r & 0 < h'_r < h_2^* \\
0 & h'_r \leq 0 
\end{cases}
\]
\[
r_{S2} = \begin{cases} 
1 & h'_s \geq h_{max,2} \\
h'_s & 0 < h'_s < h_{max,2} \\
0 & h'_s \leq 0 
\end{cases}
\]

If the propagation of the four rays in the image model was fully coherent the propagation effect could be determined by Eq. (191) but in order to take into account averaging and incoherent effects as described in Section 0, the coherence coefficient \( F_2, F_3, \) and \( F_4 \) describing the coherence between ray no. 2, 3, and 4 respectively and the direct ray have to be determined.

The coherence coefficient \( F_2 \) of ray no. 2 is calculated by Eq. (210) where the coherence coefficients \( F_1, F_3, F_4, \) and \( F_5 \) are calculated as described in Section 0. \( \rho_1 \) is the transversal separation calculated by Eq. (211). \( k_0 \) is the wave number at the ground and \( r_2 \) is the roughness of the source side terrain segment. In case of propagation through a scattering
zone $F_s$ is the coherence coefficient calculated as described in Section 5.19. Otherwise $F_s = 1$.

$$F_2(f) = F_j(f, \Delta \tau_s) F_{\Delta t}(f, \Delta \tau_s, \Delta \tau_{s+}) F_r(f, C_i^2, C_T^2, t_{\text{mean}}, \bar{e}_s, \rho_1, d'_1) F_s(k_0, \psi_{GS}, r_1) F_r(f)$$  \hspace{1cm} (210)

$$\rho_1 = \frac{2h_{s1}' h_{R1}'}{h_{s1}' + h_{R1}'}$$  \hspace{1cm} (211)

The coherence coefficient $F_3$ of ray no. 3 is calculated by Eq. (212) where the coherence coefficients $F_1$, $F_\Delta$, $F_s$, and $F_r$ are calculated as described in Section 0. $\rho_2$ is the transversal separation calculated by Eq. (213), $k_0$ is the wave number at the ground and $r_2$ is the roughness of the receiver side terrain segment.

$$F_3(f) = F_j(f, \Delta \tau_R) F_{\Delta t}(f, \Delta \tau_R, \Delta \tau_{R+}) F_r(f, C_i^2, C_T^2, t_{\text{mean}}, \bar{e}_R, \rho_2, d'_2) F_s(k_0, \psi_{GR}, r_2) F_r(f)$$  \hspace{1cm} (212)

$$\rho_2 = \frac{2h_{s2}' h_{R2}'}{h_{s2}' + h_{R2}'}$$  \hspace{1cm} (213)

The coherence coefficient $F_4$ of ray no. 4 is calculated by Eq. (214).

$$F_4(f) = F_j(f, \Delta \tau_s + \Delta \tau_R) F_{\Delta t}(f, \Delta \tau_s + \Delta \tau_R, \Delta \tau_{s+} + \Delta \tau_{R+}) F_r(f, C_i^2, C_T^2, t_{\text{mean}}, \bar{e}_R, \rho_3, d'_3) F_s(k_0, \psi_{GS}, r_3) F_r(k_0, \psi_{GR}, r_4) F_s(f)$$  \hspace{1cm} (214)

Now the propagation effect can be determined by Eq. (215) if shadow zone effects occur neither on the source side of the screen nor on the receiver side.

$$|\hat{p}_G| = \sqrt{1 + F_2 \frac{w_{Q1} \hat{Q}_1 \hat{p}_2}{\hat{p}_1} + F_3 \frac{w_{Q2} \hat{Q}_2 \hat{p}_3}{\hat{p}_1} + F_4 \frac{w_{Q2} \hat{Q}_2 \hat{p}_4}{\hat{p}_1} + \left(1 - F_2^2 \right) \left(1 - F_3^2 \right) \left(1 - F_4^2 \right)}$$  \hspace{1cm} (215)

The incoherent reflection coefficients $R_1$ and $R_2$ in Eq. (215) are determined by Eq. (216).
\[ R_1 = \Re (f, \hat{Z}_{g1}) \]
\[ R_2 = \Re (f, \hat{Z}_{g2}) \]

(216)

If \( d_1' > 0.95 d_{SZ,1} \) and \( d_2' \leq 0.95 d_{SZ,2} \) shadow zone effects will occur on the source side of the screen and \( |p_G| \) has to be calculated by Eq. (217) where \( |p_G|_{\text{Eq.215}} \) indicates the value calculated by Eq. (215) with modified values of \( Q_1, p_2 \) and \( p_4 \).

\[
|\hat{p}_G| = 10 \frac{\Delta L_{SZ,f}}{20} |\hat{p}_G|_{\text{Eq.215}}
\]

where

\[
\Delta L_{SZ,1}(f) = ShadowZoneShielding \left( f, d_1', h_{s1}', h_{r1}', \xi_{s1}, c_{0s}, d_{SZ,1} \right)
\]

(217)

\[
\hat{Q}_1(f) = \hat{Q}(f, \tau_{1}, 0, \hat{Z}_{g1}(f))
\]

\[ \hat{p}_2 = \hat{p}_1 \]
\[ \hat{p}_4 = \hat{p}_3 \]

If \( d_2' > 0.95 d_{SZ,2} \) and \( d_1' \leq 0.95 d_{SZ,1} \) shadow zone effects will occur on the receiver side of the screen and \( |p_G| \) has to be calculated by Eq. (218) where \( |p_G|_{\text{Eq.215}} \) indicates the value calculated by Eq. (215) with modified values of \( Q_2, p_3 \) and \( p_4 \).

\[
|\hat{p}_G| = 10 \frac{\Delta L_{SZ,f}}{20} |\hat{p}_G|_{\text{Eq.215}}
\]

where

\[
\Delta L_{SZ,2}(f) = ShadowZoneShielding \left( f, d_2', h_{s2}', h_{r2}', \xi_{r2}, c_{0r}, d_{SZ,2} \right)
\]

(218)

\[
\hat{Q}_2(f) = \hat{Q}(f, \tau_{2}, 0, \hat{Z}_{g2}(f))
\]

\[ \hat{p}_3 = \hat{p}_1 \]
\[ \hat{p}_4 = \hat{p}_2 \]

If \( d_1' > 0.95 d_{SZ,1} \) and \( d_2' > 0.95 d_{SZ,2} \) shadow zone effects will occur on both sides of the screen and \( |p_G| \) has to be calculated by Eq. (219) where \( |p_G|_{\text{Eq.215}} \) indicates the value calculated by Eq. (215) with modified values of \( Q_1, Q_2, p_2, p_3, \) and \( p_4 \).
\[ |\hat{p}_G| = 10^{\frac{\Delta L_{SZ,1}(f)}{20}} 10^{\frac{\Delta L_{SZ,2}(f)}{20}} |\hat{p}_G| \quad \text{Eq. 215} \]

where
\[ \Delta L_{SZ,1}(f) = ShadowZoneShielding \left( f, d_i', h_{S1}', h_{R1}', \xi, c_{05}, d_{SZ,1} \right) \]
\[ \Delta L_{SZ,2}(f) = ShadowZoneShielding \left( f, d_i', h_{S2}', h_{R2}', \xi, c_{05}, d_{SZ,2} \right) \]
\[ \hat{Q}_1(f) = \hat{Q}(f, \tau_{1S}, 0, \hat{Z}_{G1}(f)) \]
\[ \hat{Q}_2(f) = \hat{Q}(f, \tau_{1R}, 0, \hat{Z}_{G2}(f)) \]
\[ \hat{p}_4 = \hat{p}_1 \]
\[ \hat{p}_3 = \hat{p}_1 \]
\[ \hat{p}_2 = \hat{p}_1 \]

5.14.2 General Model

If the terrain has been found to contain one screen with two significant diffracting edge, the terrain effect is calculated by Sub-model 5 described in this section. An example of such a terrain is shown in Figure 23 where the three segments denoted 4-6 form a thick screen. The remaining five segments will be considered reflecting surfaces. Segments 1–3 will form the surface on the source side of the screen while segments 7–8 form the surface on the receiver side.

**Figure 23**

Example of a segmented terrain with one screen having two diffracting edges.
At this point it is assumed that the screen part of the terrain profile has already been identified and therefore that the number of segments before and after the screen which are considered reflecting segments are known. If the part of the input terrain forming the screen shape contains more than four ground points the screen shape is reduced to four points as described in Section 5.21.

The screen is defined by the following point numbers in the terrain profile (numbered 1 to \(N_{ts}+1\) where \(N_{ts}\) is the number of segments in the terrain profile).

- \(i_{SCR,1}\) terrain point number closest to the source
- \(i_{SCR,2}\) terrain point number closest to the receiver
- \(i_{SCR,T1}\) terrain point number of the diffracting edge closest to source
- \(i_{SCR,T2}\) terrain point number of the diffracting edge closest to receiver

Therefore, the line segment representing the screen face closest to the source has the end coordinates \(W_1 = (x_{i_{SCR,1}}, z_{i_{SCR,1}})\) and \(T_1 = (x_{i_{SCR,T1}}, z_{i_{SCR,T1}})\) while the line segment representing the screen face closest to the receiver has the end coordinates \(W_2 = (x_{i_{SCR,2}}, z_{i_{SCR,2}})\) and \(T_2 = (x_{i_{SCR,T2}}, z_{i_{SCR,T2}})\). The line segment between \(T_1\) and \(T_2\) is the top of the screen. Possible terrain points between point no. \(i_{SCR,1}\) and \(i_{SCR,T1}\), between point no. \(i_{SCR,T1}\) and \(i_{SCR,T2}\), and between point no. \(i_{SCR,T2}\) and \(i_{SCR,2}\) are ignored. In this case the flow resistivity \(\sigma_{i_{SCR,T1-1}}\) is used as representative to the source side screen face and \(\sigma_{i_{SCR,T2}}\) is used as representative to the receiver side screen face.

The number of reflecting segments before the screen will therefore be \(i_{SCR,1-1}\) numbered from \(N_{S1} = 1\) to \(N_{S2} = i_{SCR,1-1}\) while the number of reflecting segments after the screen will be \(N_{ts}+1\) numbered from \(N_{R1} = i_{SCR,2}\) to \(N_{R2} = N_{ts}\).

The base model will now used for all combinations of segments of the source side \((i_1 = N_{S1}\) to \(N_{S2}\)) and on the receiver side \((i_2 = N_{R1}\) to \(N_{R2}\)). For each case of \(i_1\) and \(i_2\) the coordinates to use in the base model are:

- \(T_1 = (x_{T1}, z_{T1}) = (x_{i_{SCR,T1}}, z_{i_{SCR,T1}})\)
- \(T_2 = (x_{T2}, z_{T2}) = (x_{i_{SCR,T2}}, z_{i_{SCR,T2}})\)
- \(W_1 = (x_1, z_1) = (x_{i_{SCR,1}}, z_{i_{SCR,1}})\)
- \(W_2 = (x_2, z_2) = (x_{i_{SCR,2}}, z_{i_{SCR,2}})\)
- \(Z_S = Z_{i_{SCR,T1-1}}\)
- \(Z_R = Z_{i_{SCR,T2}}\)
- \(P_{S1} = (x_{S1}, z_{S1}) = (x_{i_1}, z_{i_1})\)
\[
\begin{align*}
\mathbf{P}_{S2} &= (x_{S2}, z_{S2}) = (x_{i1+1}, z_{i1+1}) \\
Z_{G1} &= Z_{i1} \\
w''_1(f) &= w''_{i1}(f) \\
\mathbf{P}_{R1} &= (x_{R1}, z_{R1}) = (x_{i2}, z_{i2}) \\
\mathbf{P}_{R2} &= (x_{R2}, z_{R2}) = (x_{i2+1}, z_{i2+1}) \\
Z_{G2} &= Z_{i2} \\
w''_2(f) &= w''_{i2}(f)
\end{align*}
\]

The base model is used to calculate the screen effect \(|p_{\text{SCR}}|\) and the ground effect \(|p_{G}|\). The former will be identical for all combinations of terrain segment and has to be calculated only once while the latter will vary for each combination of terrain terrain segments and will be denoted \(|p_{G,i_1,i_2}|\) for segment \(i_1\) on the source side of the screen and \(i_2\) on the receiver side.

Based on the sum of Fresnel-zone weights \(w''_{i1}(f) = w''_{1}(f)\) and \(w''_{i2}(f) = w''_{2}(f)\) on each side of the screen the Fresnel-zone weights are normalized as shown in Eq. (220) and the weights \(w_{Q1}\) and \(w_{Q2}\) used the base model are determined.
\[ w_{t1}(f) = \sum_{i=N_{x1}}^{N_{x2}} w_i^n(f) \]
\[ w_{t2}(f) = \sum_{i=2=N_{x1}}^{N_{x2}} w_i^n(f) \]
\[ \Delta w_{t1}(f) = \begin{cases} w_{t1}(f) - 1 & \text{if } w_{t1}(f) > 1 \\ 0 & \text{if } w_{t1}(f) \leq 1 \end{cases} \]
\[ \Delta w_{t2}(f) = \begin{cases} w_{t2}(f) - 1 & \text{if } w_{t2}(f) > 1 \\ 0 & \text{if } w_{t2}(f) \leq 1 \end{cases} \]
\[ \Delta w_i(f) = \Delta w_{t1}(f) + \Delta w_{t2}(f) \]
\[ w'_{t1}(f) = \begin{cases} \frac{w_i^n(f)}{w_{t1}(f)} \left( \frac{\Delta w_{t1}(f)}{\Delta w_i(f)} + 1 \right) & \text{if } w_{t1}(f) > 1 \\ 0 & \text{if } w_{t1}(f) \leq 1 \end{cases} \]  (220)
\[ w'_{t2}(f) = \begin{cases} \frac{w_i^n(f)}{w_{t2}(f)} \left( \frac{\Delta w_{t2}(f)}{\Delta w_i(f)} + 1 \right) & \text{if } w_{t2}(f) > 1 \\ 0 & \text{if } w_{t2}(f) \leq 1 \end{cases} \]
\[ w_{Q1}(f) = \begin{cases} 1 & \text{if } w_{t1}(f) \geq 1 \\ w_i^n(f) & \text{if } w_{t1}(f) < 1 \end{cases} \]
\[ w_{Q2}(f) = \begin{cases} 1 & \text{if } w_{t2}(f) \geq 1 \\ w_i^n(f) & \text{if } w_{t2}(f) < 1 \end{cases} \]

Finally the sound pressure level \( \Delta L_5 \) of Sub-model 5 for a terrain with one screen having two edges is calculated according to Eq. (221).

\[ \Delta L_5 = 20 \log \left( \hat{p}_{SCR}(f) \prod_{i=N_{x1}}^{N_{x2}} \prod_{j=1}^{N_{x1}} \hat{p}_{G_{i,j,2}}(f) w_i^n(f)w_j^n(f) \right) \]  (221)
5.15 Sub-Model 6: Terrain with Two Screens

If the terrain has been found to contain two screens, each with one significant diffracting edge, the terrain effect is calculated by Sub-model 6 described in this section. The description has been divided into two parts. In Section 5.15.1 the base model is described where there is one reflecting surface in the regions before the first screen, after the second screen, and between the screens. In Section 0 the general model is described which can have any number of segments in each region.

5.15.1 Base Model

In the base model there is one reflecting surface in source region before the first wedge-shaped screen, in the receiver region after the second wedge-shaped screen, and in the middle region between the two screens as shown in Figure 24. The first wedge is defined by the points \( W_{11}, T_1, \) and \( W_{12} \) and the second wedge by the points \( W_{21}, T_2, \) and \( W_{22}. \) The reflecting surfaces are defined by \( P_{S1}P_{S2} \) in the source region, by \( P_{M1}P_{M2} \) in the middle region of the screen and by \( P_{R1}P_{R2} \) in the receiver region. \( S_i \) and \( R_i \) are the image of the source \( S \) and receiver \( R \) reflected in the source and receiver segment, respectively. \( T_{1i} \) and \( T_{2i} \) are the image of \( T_1 \) and \( T_2 \) reflected in the middle segment, respectively. The rays shown in the figure are straight line rays corresponding to a non-refracting atmosphere. For refracting atmospheres the rays will be arcs of circles instead as described in Section 5.5.

![Figure 24](image)

*Figure 24*

Definition of geometry for the base model.

In the base model the so-called the image method is used where the sound pressure at the receiver is the sum of coherent contributions from eight rays as expressed by Eq. (222). \( p_1 \) is the diffracted sound pressure at the receiver from the source over the top of the screens. \( p_2 \) is the diffracted sound pressure at the receiver from the image source, \( p_3 \) is the diffracted sound pressure at the image receiver from the source and \( p_4 \) is the diffracted sound...
pressure at the image receiver from the image source. \( p_5 \) to \( p_8 \) correspond to \( p_1 \) to \( p_4 \) but the rays are in this case reflected by the ground segment between the screens. The spherical wave reflection coefficient \( Q_i \) in the source region is calculated by replacing \( R \) with \( T_1 \). Similarly, \( Q_i \) in the receiver region is calculated by replacing \( S \) with \( T_2 \) and \( Q_2 \) in the middle region is calculated by replacing \( S \) and \( R \) with \( T_1 \) and \( T_2 \).

\[
\hat{\rho} = \hat{\rho}_1 + \hat{Q}_1 \hat{\rho}_2 + \hat{Q}_3 \hat{\rho}_3 + \hat{Q}_4 \hat{\rho}_4 + \hat{Q}_5 \hat{\rho}_5 + \hat{Q}_6 \hat{\rho}_6 + \hat{Q}_7 \hat{\rho}_7 + \hat{Q}_8 \hat{\rho}_8 \quad (222)
\]

In order to apply the Fresnel-zone interpolation principle described in Section 5.8 the propagation effect is obtained by expressing the sound pressure relative to the free-field sound pressure \( p_0 \) and screen effect and ground effect are separated as shown in Eq. (223). Allthough not indicated all variables in the equation are a function of the frequency. In this equation \( p_{1,\text{ff}}/p_0 \) is the effect of the screens in free space and the term in brackets is the effect of the ground in excess of the screen effect. The reason for denoting the diffracted sound pressure from source to receiver \( p_{1,\text{ff}} \) in the screen effect part of the equation and \( p_1 \) in ground effect is that different equivalent sound speed profiles are used in the two cases. The linearization used to calculate \( p_{1,\text{ff}} \) is independent of the position of the reflecting ground surfaces.

\[
\frac{\hat{\rho}}{\hat{\rho}_0} = \frac{\hat{\rho}_{1,\text{ff}}}{\hat{\rho}_0} \left( 1 + \hat{Q}_1 \frac{\hat{\rho}_2}{\hat{\rho}_1} + \hat{Q}_3 \frac{\hat{\rho}_4}{\hat{\rho}_1} + \hat{Q}_4 \frac{\hat{\rho}_5}{\hat{\rho}_1} + \hat{Q}_5 \frac{\hat{\rho}_6}{\hat{\rho}_1} \right. \\
+ \hat{Q}_6 \frac{\hat{\rho}_7}{\hat{\rho}_1} + \hat{Q}_7 \frac{\hat{\rho}_8}{\hat{\rho}_1} + \hat{Q}_8 \frac{\hat{\rho}_8}{\hat{\rho}_1} \right) \quad (223)
\]

If case of reduced efficiency of the ground reflection on the source or receiver side of the screen it may be necessary to modify \( Q_1 \), \( Q_2 \) and \( Q_3 \). In Eq. (224) the modified values are denoted \( Q'_1 \), \( Q'_2 \) and \( Q'_3 \) and are obtained by multiplying the original values by a real number \( w_Q \) between 0 and 1. The value 1 indicates a fully efficient ground reflection while 0 indicates no reflection at all. The calculation of \( w_{Q1} \), \( w_{Q1} \) and \( w_{Q3} \) will be described in the general model in Section 0. As mentioned above the term outside the brackets is the effect of the screen in free space and is denoted \( p_{\text{SCR}} \) while the term inside the brackets is the effect of the ground and is denoted \( p_G \).
\[
\frac{\hat{p}}{\hat{p}_0} = \frac{p_{1,\theta}}{\hat{p}_0} \left( \frac{1 + \hat{Q}'_1 p_2}{p_1} + \hat{Q}'_2 \frac{p_4}{p_1} + \hat{Q}'_3 \frac{p_5}{p_1} \right) = \hat{p}_{SCR} \hat{p}_G
\]

where

\[
\hat{Q}'_1 = w_{01} \hat{Q}_1 \\
\hat{Q}'_2 = w_{02} \hat{Q}_2 \\
\hat{Q}'_3 = w_{03} \hat{Q}_3
\]

The first step is to determine the variables that have to be used to calculate the diffracted sound pressures \( p_{1,\theta} \). \( p_1, p_2, p_3, p_4, p_5, p_6, p_7 \) and \( p_8 \) by the auxiliary function \( p_{2wedge} \) as shown in Eq. (225). \( Z_{1S}(f), Z_{1R}(f), Z_{2S}(f) \) and \( Z_{2R}(f) \) are the impedances of the source and receiver side wedge face of the first and second screen, respectively.

\[
\hat{p}(f) = p_{2wedge} \left( f, \beta_1, \theta_{1S}, \beta_2, \theta_{2S}, \beta_3, \theta_{2R}, \tau_S, \tau_M, R_S, R_M, R_G, \hat{Z}_{1S}(f), \hat{Z}_{1R}(f), \hat{Z}_{2S}(f), \hat{Z}_{2R}(f) \right)
\]

To calculate the diffracted sound pressure the input variables in Eq. (225) which are defined in Section 5.7.3 have to be determined. The first wedge-shaped screen are defined by the diffracting edge \( T_1 = (x_{T1}, z_{T1}) \), the start of the wedge \( W_{11} = (x_{11}, z_{11}) \) closest to source and the end of the wedge \( W_{12} = (x_{12}, z_{12}) \) closest to receiver. The second wedge-shaped screen are defined by the diffracting edge \( T_2 = (x_{T2}, z_{T2}) \), the start of the wedge \( W_{21} = (x_{21}, z_{21}) \) closest to source and the end of the wedge \( W_{22} = (x_{22}, z_{22}) \) closest to receiver. The source region ground segment is defined by the end points \( P_{S1} = (x_{S1}, z_{S1}) \) and \( P_{S2} = (x_{S2}, z_{S2}) \) and the ground impedance \( Z_{G1}(f) \), the middle region ground segment by the end points \( P_{M1} = (x_{M1}, z_{M1}) \) and \( P_{M2} = (x_{M2}, z_{M2}) \) and the ground impedance \( Z_{G2}(f) \), and the receiver region ground segment by the end points \( P_{R1} = (x_{R1}, z_{R1}) \) and \( P_{R2} = (x_{R2}, z_{R2}) \) and the ground impedance \( Z_{G3}(f) \).

The variables used to calculate \( p_{1,\theta} \) is determined according to Eqs. (226) to (228). \( h''_{SCR} \) is determined by Eq. (22). When calculating \( p_{1,\theta} \) the equivalent linear sound speed profile is independent of the frequency.
\[(x'_T, z'_T, h_{SCR}) = \text{NormLine}(x_{SG}, z_{SG}, x_{RG}, z_{RG}, x'_T, z'_T)\]
\[(x'_T, z'_T, h_{SCR2}) = \text{NormLine}(x_{SG}, z_{SG}, x_{RG}, z_{RG}, x'_T, z'_T)\]
\[d_{SCR1} = \text{Length}(x_{SG}, z_{SG}, x'_T, z'_T)\]
\[d_{SCR2} = \text{Length}(x'_T, z'_T, x_{RG}, z_{RG})\]
\[(\xi, c_{0S}, NA) = \text{CalcEqSSP}(h_s, h_{SCR}, z_0, A, B, C)\]
\[\left(\tau_s, R_s, \Delta \theta_s, NA, d_{SZ,S}\right) = \text{DirectRay}(d_{SCR}, h_s, h_{SCR}, \xi, c_{0S})\]
\[(\xi, c_{0M}, NA) = \text{CalcEqSSP}(h_{SCR}^*, h_{SCR}, z_0, A, B, C)\]
\[\left(\tau_M, R_M, \Delta \theta_M, NA, d_{SZ,M}\right) = \text{DirectRay}(d_{SCR}, h_{SCR}, h_{SCR}, \xi, c_{0M})\]
\[(\xi, c_{0R}, NA) = \text{CalcEqSSP}(h_R, h_{SCR}, z_0, A, B, C)\]
\[\left(\tau_R, R_R, \Delta \theta_R, NA, d_{SZ,R}\right) = \text{DirectRay}(d_{SCR}, h_R, h_{SCR}, \xi, c_{0R})\]

The wedge angle \(\beta\) and diffraction angles \(\theta_s\) and \(\theta_R\) can now be determined by Eq. (227) on basis of the wedge coordinates of the first screen.

\[
\begin{align*}
\beta_1 &= \arctan\left(\frac{z_{11} - z_{T1}}{x_{T1} - x_{11}}\right) + \frac{\pi}{2} \\
\beta_2 &= \arctan\left(\frac{z_{12} - z_{T1}}{x_{T1} - x_{12}}\right) + \frac{\pi}{2} \\
\theta_{11} &= \arctan\left(\frac{z_{S} - z_{T1}}{x_{T1} - x_{S}}\right) + \frac{\pi}{2} \\
\theta_{12} &= \arctan\left(\frac{z_{R} - z_{T1}}{x_{T1} - x_{R}}\right) + \frac{\pi}{2} \\
\theta_s &= 2\pi - \theta_{11} - \beta_{11} - \Delta \theta_s \\
\theta_R &= \theta_{12} - \beta_{12} + \Delta \theta_M
\end{align*}
\]

The wedge angle \(\beta\) and diffraction angles \(\theta_s\) and \(\theta_R\) can now be determined by Eq. (228) on basis of the wedge coordinates of the first screen.
The numerical value of the screen effect $|p_{SCR}|$ is now determined by Eq. (229) where $p_{1,ff}(f)$ is calculated by Eq. (225) using the values of the input variables given in Eqs. (226) through (228). $R_{SR}$ is the source-receiver distance

$$|\hat{p}_{SCR}(f)| = |\hat{p}_{1,ff}(f)| R_{SR} \tag{229}$$

In the calculation of $p_1$ to $p_8$ the linearization of the sound speed profile used to determine the diffraction angles will still be independent of the frequency in the same way as described for $p_{1,ff}$ but the travel times and travel distances in the ground effect calculation will depend on the frequency as described in Section 5.5.3.

To calculate the sound pressures $p_1$ to $p_8$ in the ground attenuation part of Eq. (224) the first step is to determine the height $h'_{S1}$ of the source S and the height $h'_{R1}$ of the screen edge $T_1$ above the terrain segment on the source side of the first screen and the distances $d'_1$ from S to $T_1$, $d'_{11}$ from S to the start of the segment, and $d'_{12}$ from S to the end of the segment measured along the terrain segment. This is done by the auxiliary function $SegmentVariables$ described in Section 5.23.15 as shown in Eq. (230). In the same way the height $h'_{S2}$ of the screen edge $T_1$ and the height $h'_{R2}$ of the screen edge $T_2$ above the terrain segment between the screens and the distances $d'_2$ from $T_1$ to $T_2$, $d'_{21}$ from $T_1$ to the start of the segment, and $d'_{22}$ from $T_1$ to the end of the segment measured along the terrain segment. Finally, the height $h'_{S3}$ of the screen edge $T_2$ and the height $h'_{R3}$ of the receiver R above the terrain segment on the receiver side of the second screen, and the distances $d'_3$ from $T_2$ to R, $d'_{31}$ from $T_2$ to the start of the segment, and $d'_{32}$ from $T_2$ to the end of the segment measured along the terrain segment. This is also shown in Eq. (230).
\[ (d_1', h_{S1}', h_{R1}', d_{11}', d_{12}') = \text{SegmentVariables}(x_S', z_S', x_{T1}, z_{T1}, x_S, z_S, x_{S2}, z_{S2}) \]
\[ (d_2', h_{S2}', h_{R2}', d_{21}', d_{22}') = \text{SegmentVariables}(x_{T1}, z_{T1}, x_{T2}, z_{T2}, x_{M1}, z_{M1}, x_{M2}, z_{M2}) \]  
\[ (d_3', h_{S3}', h_{R3}', d_{31}', d_{32}') = \text{SegmentVariables}(x_{T2}, z_{T2}, x_R, z_R, x_{R1}, z_{R1}, x_{R2}, z_{R2}) \]

When calculating the sound pressure \( p_1 \) the diffraction angles are the same as used \( p_{1,H} \).
When calculating the sound pressures \( p_2 \) to \( p_8 \) diffraction angles \( \theta_{S1} \) and \( \theta_{M1} \) of the first screen for the image source and image screen top \( T'_2 \) have to be determined as shown in Eq. (231). The angles \( \beta_1, \beta_{11}, \) and \( \beta_{21} \) are the same as calculated in Eq. (227). Due to numerical difficulties in strong upward refraction cases the image point angles \( \theta_1 \) and \( \theta_2 \) in Eq. (231) may become larger than corresponding angles of the direct ray defined in Eq. (227). This may lead to erroneous results and in such cases the image point angle shall be set equal to the direct ray angle.

\[ (\text{NA, NA, NA, NA, NA}, \Delta \theta_{S1}, \text{NA, NA}) = \text{ReflectedRay}(d_1', h_{S1}', h_{R1}', \xi_S, c_{OS}) \]
\[ (\text{NA, NA, NA, NA}, \Delta \theta_{M1}, \text{NA, NA, NA}) = \text{ReflectedRay}(d_2', h_{S2}', h_{R2}', \xi_M, c_{OM}) \]
\[ (x_{S1}, z_{S1}) = \text{ImagePoint}(x_{S1}, z_{S1}, x_{S2}, z_{S2}, x_S, z_S) \]
\[ (x_{M1}, z_{M1}) = \text{ImagePoint}(x_{M1}, z_{M1}, x_{M2}, z_{M2}, x_{T2}, z_{T2}) \]

\[ \theta_1 = \arctan \left( \frac{z_{S1} - z_{T1}}{x_{T1} - x_{S1}} \right) + \frac{\pi}{2} \]  
\[ \theta_2 = \arctan \left( \frac{z_{M1} - z_{T1}}{x_{M1} - x_{T1}} \right) + \frac{\pi}{2} \]
\[ \theta_{S1} = 2\pi - \theta_1 - \beta_1 - \Delta \theta_{S1} \]
\[ \theta_{M1} = \theta_2 - \beta_2 + \Delta \theta_{M1} \]

For the second screen the diffraction angles \( \theta_{S21} \) and \( \theta_{R1} \) for the image screen top \( T'_1 \) and the image receiver have to be determined as shown in Eq. (232). The angles \( \beta_2, \beta_{21}, \) and \( \beta_{22} \) are the same as calculated in Eq. (228). Due to numerical difficulties in strong upward refraction cases the image point angles \( \theta_1 \) and \( \theta_2 \) in Eq. (232) may become larger than corresponding angles of the direct ray defined in Eq. (228). This may lead to erroneous results and in such cases the image point angle shall be set equal to the direct ray angle.
(NA, NA, NA, NA, NA, ΔθM, NA, NA) = ReflectedRay\(d', h_{S2}', h_{R2}', \xi_M, c_{0M}\)

(NA, NA, NA, NA, ΔθR, NA, NA, NA) = ReflectedRay\(d', h_{S3}', h_{R3}', \xi_R, c_{0R}\)

\((x_{M1}, z_{M1}) = ImagePoint(x_{M1}, z_{M1}, x_{M2}, z_{M2}, x_{T1}, z_{T1})\)

\((x_{R1}, z_{R1}) = ImagePoint(x_{R1}, z_{R1}, x_{R2}, z_{R2}, x_{R}, z_{R})\)

\[\begin{align*}
\theta_1 &= \arctan\left(\frac{z_{M} - z_{T2}}{x_{T2} - x_{M}}\right) + \frac{\pi}{2} \\
\theta_2 &= \arctan\left(\frac{z_{R} - z_{T2}}{x_{R} - x_{T2}}\right) + \frac{\pi}{2} \\
\theta_{M2i} &= 2π - \theta_1 - \beta_2 - Δθ_M \\
\theta_R &= \theta_2 - \beta_2 + Δθ_R
\end{align*}\]  \(232\)

The travel times and travel distances used to calculate the sound pressures \(p_2\) to \(p_8\) are based on a frequency dependent linear sound speed profile and will therefore be a function of the frequency.

For the variables of the source side of the first screen the modified frequency dependent equivalent linear sound speed profile is determined by the function \(CalcEqSSPGround\) described in Section 5.5.3 as shown in Eq. (233) for average refraction and for upper refraction (indicates by +).

\[\begin{align*}
(\xi_5(f), c_{05}(f), \xi_5, c_{05}) &= CalcEqSSPGround(h_{S1}', h_{R1}', \tilde{Z}_G(f), z_0, A, B, C) \\
(\xi_5, c_{05}(f), NA, NA, NA) &= CalcEqSSPGround(h_{S1}', h_{R1}', \tilde{Z}_G(f), z_0, A, B, C)
\end{align*}\]  \(233\)

The ray variables on the source side of the first screen are determined for the direct ray and the reflected ray in Eq. (234) for average refraction and upper refraction using the procedures \(DirectRay\) and \(ReflectedRay\) described in Sections 5.5.4 and 5.5.5. NA indicates that a calculated variable is not used. If the calculation by \(DirectRay\) shows that the screen edge \(T_2\) is in a shadow zone (\(\xi_5 < 0\) and \(d'_1 > 0.95\ d_{SZ,1}\) where \(d_{SZ,1}\) is the distance to the shadow zone as defined in Section 5.5.4) calculations by \(ReflectedRay\) are not carried out. The variables \(r, R, \psi_G,\) and \(Δr\) are in the following equations of this section a function of the frequency.
The travel time differences $\Delta \tau_S$ and $\Delta \tau_{S+}$ for average and upper refraction are determined by Eq. (235).

\[
\begin{align*}
\Delta \tau_S &= \text{TravelTimeDiff} (\tau_{2S}, \tau_{1S}) \\
\Delta \tau_{S+} &= \text{TravelTimeDiff} (\tau_{2S+}, \tau_{1S+})
\end{align*}
\]  

The spherical-wave reflection coefficient $Q_1$ for the terrain reflection on the source side of the screen is calculated by Eq. (236).

\[
\hat{Q}_1 = \hat{Q}(f, \tau_{2S}, \psi_G, \hat{\zeta}_{G1})
\]  

For the variables between the two screens the modified frequency dependent equivalent linear sound speed profile is determined by the function $\text{CalcEqSSPGround}$ described in Section 5.5.3 as shown in Eq. 237 for average refraction and for upper refraction (indicates by $+$).

\[
\begin{align*}
(\xi_M(f), c_{0M}(f), \bar{c}_M, \hat{\xi}_M, c_{0M}) &= \text{CalcEqSSPGround} \left(h'_{52}, h'_{r2}, \hat{Z}_{G2}(f), z_0, A, B, C \right) \\
(\xi_{M+}(f), c_{0M+}(f), NA, NA, NA) &= \text{CalcEqSSPGround} \left(h'_{52}, h'_{r2}, \hat{Z}_{G2}(f), z_0, A_+, B_+, C \right)
\end{align*}
\]

The ray variables between the two screens are determined for the direct ray and the reflected ray in Eq. (238) for average and upper refraction using the procedures $\text{DirectRay}$ and $\text{ReflectedRay}$ described in Sections 5.5.4 and 5.5.5. NA indicates that a calculated variable is not used. If the calculation by $\text{DirectRay}$ shows that the receiver is in a shadow zone ($\xi_M < 0$ and $d' > 0.95 d_{SZ,2}$ where $d_{SZ,2}$ is the distance to the shadow zone as defined in Section 5.5.4) calculations by $\text{ReflectedRay}$ are not carried out. The variables $\tau, R, \psi_G$, and $\Delta \tau$ are in the following equations of this section a function of the frequency.
\[
(\tau_{1M}, R_{1M}, NA, NA, d_{SZ,2}) = DirectRay(d'_2, h'_3, h'_R2, \xi_M(f), c_{0M}(f))
\]
\[
(\tau_{1M+}, NA, NA, NA, NA) = DirectRay(d'_2, h'_3, h'_R2, \xi_M(f), c_{0M+}(f))
\]
\[
(\tau_{2M}, R_{2M}, NA, NA, NA, NA, Na, NA, \psi_{GM}, NA) = ReflectedRay(d'_2, h'_3, h'_R2, \xi_M(f), c_{0M+}(f))
\]
\[
(\tau_{2M+}, NA, NA, NA, NA, NA, Na, NA, NA, NA) = ReflectedRay(d'_2, h'_3, h'_R2, \xi_M(f), c_{0M+}(f))
\]

The travel time differences \(\Delta \tau_M\) and \(\Delta \tau_{M+}\) for average and upper refraction are determined by Eq. (239).

\[
\Delta \tau_M = TravelTimeDiff(\tau_{2M}, \tau_{1M})
\]
\[
\Delta \tau_{M+} = TravelTimeDiff(\tau_{2M+}, \tau_{1M+})
\]

The spherical-wave reflection coefficient \(Q_2\) for the terrain reflection on the receiver side of the screen is calculated by Eq. (240).

\[
\hat{Q}_2 = \hat{Q}(f, \tau_{2M}, \psi_{GM}, \hat{Z}_{G2})
\]

For the variables of the receiver side of the second screen the modified frequency dependent equivalent linear sound speed profile is determined by Eq. (241) for average refraction and for upper refraction (indicates by +).

\[
(\xi_R(f), c_{0R}(f), \xi_R, c_{0R}) = CalcEqSSPGround(h'_3, h'_R3, \hat{Z}_{G3}(f), z_0, A, B, C)
\]
\[
(\xi_R, (f), c_{0R+}(f), NA, NA, NA) = CalcEqSSPGround(h'_3, h'_R3, \hat{Z}_{G3}(f), z_0, A+, B+, C)
\]

The ray variables on the receiver side are determined for the direct ray and the reflected ray in Eq. (242) for average and upper refraction using the procedures DirectRay and ReflectedRay described in Sections 5.5.4 and 5.5.5. NA indicates that a calculated variable is not used. If the calculation by DirectRay shows that the receiver is in a shadow zone \((\xi_R < 0)\) and \(d'_3 > 0.95 d_{SZ,3}\) where \(d_{SZ,3}\) is the distance to the shadow zone as defined in Section 5.5.4) calculations by ReflectedRay are not carried out. The variables \(\tau, R, \psi_{GM}\), and \(\Delta \tau\) are in the following equations of this section a function of the frequency.
\[
\begin{align*}
(\tau_{1R}, R_{1R}, NA, NA, d_{S2,3}) &= DirectRay(d'_3, h'_3, h'_R, \xi_R (f), c_{0R} (f)) \\
(\tau_{1R}, NA, NA, NA, NA) &= DirectRay(d'_3, h'_3, h'_R, \xi_R (f), c_{0R} (f)) \\
(\tau_{2R}, R_{2R}, NA, NA, NA, NA, \psi_{GR}, NA) &= \text{ReflectedRay}(d'_3, h'_3, h'_R, \xi_R (f), c_{0R} (f)) \\
(\tau_{2R}, NA, NA, NA, NA, NA, NA) &= \text{ReflectedRay}(d'_3, h'_3, h'_R, \xi_R (f), c_{0R} (f))
\end{align*}
\] (242)

The travel time differences $\Delta \tau_R$ and $\Delta \tau_{R+}$ for average and upper refraction are determined by Eq. (243).

\[
\begin{align*}
\Delta \tau_R &= TravelTimeDiff(\tau_{2R}, \tau_{1R}) \\
\Delta \tau_{R+} &= TravelTimeDiff(\tau_{2R+}, \tau_{1R+})
\end{align*}
\] (243)

The spherical-wave reflection coefficient $Q_3$ for the terrain reflection on the receiver side of the screen is calculated by Eq. (244).

\[
\hat{Q}_3 = \hat{Q}(f, \tau_{2R}, \psi_{GR}, \hat{\xi}_G)
\] (244)

If the size of terrain segments on the source and receiver side is not sufficient large the ground attenuation part $|p_{G}|$ of the propagation effect has to be corrected for the limited size of the segments. This is done by calculating the Fresnel-zone weights of each segment $w_1$, $w_2$ and $w_3$ as shown in Eq. (245). Subsequently the weights are modified when source or receiver is close to the extension of the segment. The modified weights are denoted $w''_1$, $w''_2$ and $w''_3$. The modifiers $R_{S1}$, $R_{R1}$, $R_{S2}$, $R_{R2}$, $R_{S3}$, and $R_{R3}$ are calculated as shown in Eqs. (246) to (248). If source or receiver is below the extension of the segment the product of the modifiers becomes 0 which eliminates the problem of the Fresnel-zone weights $w_1$, $w_2$ and $w_3$ being undefined in this case. The Fresnel-zone weights are used in the general model described in Section 0.

\[
\begin{align*}
(w_1 (f), na, na, na, na) &= FresnelZoneW(d'_3, h'_3, h'_R, d_{11}, d_{12}, 1/16 \lambda, \xi_S, c_{0S}) \\
(w_2 (f), na, na, na, na) &= FresnelZoneW(d'_3, h'_3, h'_R, d_{21}, d_{22}, 1/16 \lambda, \xi_M, c_{0M}) \\
(w_3 (f), na, na, na, na) &= FresnelZoneW(d'_3, h'_3, h'_R, d_{31}, d_{32}, 1/16 \lambda, \xi_R, c_{0R}) \\
w_1^*(f) &= w_1(f)R_{S1}'R_{R1} \\
w_2^*(f) &= w_2(f)R_{S2}'R_{R2} \\
w_3^*(f) &= w_3(f)R_{S3}'R_{R3}
\end{align*}
\] (245)
\[ h_{\text{max},1} = \text{Min}(0.0005(x_T - x_S), 0.2) \]
\[ h''_1 = \text{Min}(h_s, h_{\text{max},1}) \]
\[ r_{S1} = \begin{cases} 1 & h'_{S1} \geq h''_1 \\ \frac{h'_{S1}}{h''_1} & 0 < h'_{S1} < h''_1 \\ 0 & h'_{S1} \leq 0 \end{cases} \]
\[ r_{R1} = \begin{cases} 1 & h'_{R1} \geq h_{\text{max},1} \\ \frac{h'_{R1}}{h_{\text{max},1}} & 0 < h'_{R1} < h_{\text{max},1} \\ 0 & h'_{R1} \leq 0 \end{cases} \]

\[ h_{\text{max},2} = \text{Min}(0.0005(x_T - x_{T1}), 0.2) \]
\[ r_{R2} = \begin{cases} 1 & h'_{R2} \geq h''_2 \\ \frac{h'_{R2}}{h_{\text{max},2}} & 0 < h'_{R2} < h_{\text{max},2} \\ 0 & h'_{R2} \leq 0 \end{cases} \]
\[ r_{S2} = \begin{cases} 1 & h'_{S2} \geq h_{\text{max},2} \\ \frac{h'_{S2}}{h_{\text{max},2}} & 0 < h'_{S2} < h_{\text{max},2} \\ 0 & h'_{S2} \leq 0 \end{cases} \]
\[ h_{\text{max,3}} = \text{Min}(0.0005(x_R - x_{T2})0.2) \]
\[ h_3^* = \text{Min}(h_R, h_{\text{max,3}}) \]
\[ r_{R3} = \begin{cases} 1 & h_{R2}^* \geq h_3^* \\ \frac{h_{R2}^*}{h_3^*} & 0 < h_{R2}^* < h_3^* \\ 0 & h_{R2}^* \leq 0 \\ 1 & h_{S2}^* \geq h_{\text{max,2}} \\ \frac{h_{S2}^*}{h_{\text{max,3}}} & 0 < h_{S2}^* < h_{\text{max,3}} \\ 0 & h_{S2}^* \leq 0 \end{cases} \]  \hfill (248)

If the propagation of the eight rays in the image model was fully coherent the propagation effect could be determined by Eq. (244) but in order to take into account averaging and incoherent effects as described in Section 0, the coherence coefficient \( F_2 \), to \( F_8 \) describing the coherence between ray no. 2 to 8 respectively and the direct ray have to be determined.

The coherence coefficient \( F_2 \) of ray no. 2 is calculated by Eq. (249) where the coherence coefficients \( F_2 \), \( F_3 \), \( F_4 \), and \( F_5 \) are calculated as described in Section 0, \( \rho_i \) is the transversal separation calculated by Eq. (250), \( k_0 \) is the wave number at the ground and \( r_2 \) is the roughness of the source side terrain segment. In case of propagation through a scattering zone \( F_s \) is the coherence coefficient calculated as described in Section 5.19. Otherwise \( F_s = 1 \).

\[ F_2(f) = F_f(f, \Delta \tau_S)F_{\Delta \tau}(f, \Delta \tau_S, \Delta \tau_{S+})F_r(f, C_v^2, C_T^2, t_{\text{mean}}, \bar{c}_S, \rho_1, d_1^f)F_r(k_0, \psi_{GS}, r_2)F_s(f) \]  \hfill (249)
\[ \rho_3 = \frac{2h_{S1}h_{R1}}{h_{S1}^* + h_{R1}^*} \]  \hfill (250)

The coherence coefficient \( F_3 \) of ray no. 3 is calculated by Eq. (251). \( \rho_3 \) is the transversal separation calculated by Eq. (252), \( k_0 \) is the wave number at the ground and \( r_3 \) is the roughness of the receiver side terrain segment.

\[ F_3(f) = F_f(f, \Delta \tau_R)F_{\Delta \tau}(f, \Delta \tau_R, \Delta \tau_{R+})F_r(f, C_v^2, C_T^2, t_{\text{mean}}, \bar{c}_R, \rho_3, d_3^f)F_r(k_0, \psi_{GR}, r_3)F_s(f) \]  \hfill (251)
\[ \rho_3 = \frac{2h_{S3}h_{R3}}{h_{S3}^* + h_{R3}^*} \]  \hfill (252)
The coherence coefficient $F_4$ of ray no. 4 is calculated by Eq. (253).

$$F_4(f) = F_j(f, \Delta \tau_s + \Delta \tau_R)F_{\Delta \tau}(f, \Delta \tau_s + \Delta \tau_R, \Delta \tau_{s+} + \Delta \tau_{r+})$$

$$F_e\left(f, C_v^2, C_T^2, t_{\text{mean}}, \bar{c}_s, \rho_1', d'_1\right)F_e\left(f, C_v^2, C_T^2, t_{\text{mean}}, \bar{c}_r, \rho_3, d'_3\right)F_r(k_0, \nu_{\text{GS}}, r_1)F_r(k_0, \nu_{\text{GR}}, r_3)F_s(f)$$  \hspace{1cm} (253)

The coherence coefficient $F_5$ of ray no. 5 is calculated by Eq. (254). $\rho_2$ is the transversal separation calculated by Eq. (255), $k_0$ is the wave number at the ground and $r_2$ is the roughness of the terrain segment between the screens.

$$F_5(f) = F_j(f, \Delta \tau_M)F_{\Delta \tau}(f, \Delta \tau_M, \Delta \tau_{M+})F_e\left(f, C_v^2, C_T^2, t_{\text{mean}}, \bar{c}_M, \rho_2', d'_2\right)F_r(k_0, \nu_{\text{GM}}, r_{21})F_s(f)$$  \hspace{1cm} (254)

$$\rho_2 = \frac{2h_y' h_{r2}'}{h_y' + h_{r2}'}$$  \hspace{1cm} (255)

The coherence coefficient $F_6$ of ray no. 6 is calculated by Eq. (256).

$$F_6(f) = F_j(f, \Delta \tau_s + \Delta \nu_M)F_{\Delta \nu}(f, \Delta \tau_s + \Delta \nu_M, \Delta \tau_{s+} + \Delta \nu_{M+})$$

$$F_e\left(f, C_v^2, C_T^2, t_{\text{mean}}, \bar{c}_s, \rho_1, d'_1\right)F_e\left(f, C_v^2, C_T^2, t_{\text{mean}}, \bar{c}_M, \rho_2, d'_2\right)F_r(k_0, \nu_{\text{GM}}, r_2)F_s(f)$$  \hspace{1cm} (256)

The coherence coefficient $F_7$ of ray no. 7 is calculated by Eq. (257).

$$F_7(f) = F_j(f, \Delta \tau_M + \Delta \nu_R)F_{\Delta \nu}(f, \Delta \tau_M + \Delta \nu_R, \Delta \tau_{M+} + \Delta \nu_{R+})$$

$$F_e\left(f, C_v^2, C_T^2, t_{\text{mean}}, \bar{c}_M, \rho_3, d'_3\right)F_r(k_0, \nu_{\text{GR}}, r_3)F_s(f)$$  \hspace{1cm} (257)

The coherence coefficient $F_8$ of ray no. 8 is calculated by Eq. (258).

$$F_8(f) = F_j(f, \Delta \tau_s + \Delta \nu_M + \Delta \nu_R)F_{\Delta \nu}(f, \Delta \tau_s + \Delta \nu_M + \Delta \nu_R, \Delta \tau_{s+} + \Delta \nu_{M+} + \Delta \nu_{R+})$$

$$F_e\left(f, C_v^2, C_T^2, t_{\text{mean}}, \bar{c}_s, \rho_1', d'_1\right)F_e\left(f, C_v^2, C_T^2, t_{\text{mean}}, \bar{c}_r, \rho_3, d'_3\right)F_r(k_0, \nu_{\text{GS}}, r_1)F_r(k_0, \nu_{\text{GR}}, r_3)F_s(f)$$  \hspace{1cm} (258)

Now the propagation effect can be determined by Eq. (259) if there are no shadow zone effects before, after or between the screens.
The incoherent reflection coefficients $\mathcal{R}_1$, $\mathcal{R}_2$ and $\mathcal{R}_3$ in Eq. (259) are determined by Eq. (260).

$$\mathcal{R}_1 = \Re\left(f, \hat{Z}_{g1}\right)$$

$$\mathcal{R}_2 = \Re\left(f, \hat{Z}_{g2}\right)$$

$$\mathcal{R}_3 = \Re\left(f, \hat{Z}_{g3}\right)$$

(260)

If $d' > 0.95d_{SZ,1}$ and $d'_2 \leq 0.95d_{SZ,2}$ and $d'_3 \leq 0.95d_{SZ,3}$ shadow zone effects will occur on the source side of the screen and $|p_G|$ has to be calculated by Eq. (261) where $|p_G|_{Eq.259}$ indicates the value calculated by Eq. (259) with modified values of $Q_1$ and $p_2, p_4, p_6$, and $p_8$. 

$$|p_G| = \left| \begin{array}{cccc}
1 + F_2 \frac{w_{Q1} \hat{Q}_1 \hat{p}_2}{\hat{p}_1} + F_3 \frac{w_{Q1} \hat{Q}_3 \hat{p}_3}{\hat{p}_1} + F_4 \frac{w_{Q1} \hat{Q}_1 w_{Q3} \hat{Q}_3 \hat{p}_4}{\hat{p}_1}^2 + \\
+ F_5 \frac{w_{Q2} \hat{Q}_2 \hat{p}_5}{\hat{p}_1} + F_6 \frac{w_{Q1} w_{Q2} \hat{Q}_2 \hat{p}_6}{\hat{p}_1} + \\
+ F_7 \frac{w_{Q2} \hat{Q}_2 w_{Q3} \hat{Q}_3 \hat{p}_4}{\hat{p}_1} + F_8 \frac{w_{Q1} w_{Q2} w_{Q3} \hat{Q}_3 \hat{p}_8}{\hat{p}_1} \\
\end{array} \right|$$

(259)
If \( d' > 0.95d_{SZ,1} \) and \( d'_1 < 0.95d_{SZ,1} \) and \( d'_2 < 0.95d_{SZ,2} \) shadow zone effects will occur on the receiver side of the second screen and \( |p_G| \) has to be calculated by Eq. (262) where \( |p_G|^{\text{Eq.259}} \) indicates the value calculated by Eq. (259) with modified values of \( Q_3 \) and \( p_3 \).

\[
|\hat{p}_G| = 10^{\Delta L_{SZ,1}(f) / 20} |\hat{p}_G|^{\text{Eq.259}}
\]

where

\[
\Delta L_{SZ,1}(f) = \text{ShadowZoneShielding} \left( f, d'_1, h_{S1}, h'_{R1}, \xi, c_{0S}, d_{SZ,1} \right) \\
\hat{Q}_1(f) = \hat{Q}(f, \tau_{1S}, 0, \hat{Z}_{G1}(f))
\]

If \( d'_1 > 0.95d_{SZ,1} \) and \( d'_2 \leq 0.95d_{SZ,1} \) and \( d'_3 > 0.95d_{SZ,2} \) shadow zone effects will on the source side of the first screen and on the receiver side of the second screen and \( |p_G| \) has to be calculated by Eq. (263) where \( |p_G|^{\text{Eq.259}} \) indicates the value calculated by Eq. (259) with modified values of \( Q_1, Q_3, p_2, p_3, p_4, p_6, p_7, \) and \( p_8 \).
\[ |\hat{p}_G| = 10^{\frac{\Delta L_{SZ,1}(f)}{20}} 10^{\frac{\Delta L_{SZ,3}(f)}{20}} |\hat{p}_G|^{\text{Eq.259}} \]

where
\[ \Delta L_{SZ,1}(f) = \text{Shadow Zone Shielding} \left( f, d'_1, h_{s1}', h_{r1}', \xi, c_{0,5}, d_{SZ,1} \right) \]
\[ \Delta L_{SZ,3}(f) = \text{Shadow Zone Shielding} \left( f, d'_3, h_{s3}', h_{r3}', \xi, c_{0,6}, d_{SZ,3} \right) \]
\[ \hat{Q}_1(f) = \hat{Q}(f, \tau_{1,0}, 0, \hat{Z}_{G1}(f)) \]
\[ \hat{Q}_3(f) = \hat{Q}(f, \tau_{1,0}, 0, \hat{Z}_{G3}(f)) \]
\[ \hat{p}_2 = \hat{p}_1 \]
\[ \hat{p}_3 = \hat{p}_1 \]

5.15.2 General Model

If the terrain has been found to contain two wedge-shaped screens, the terrain effect is calculated by Sub-model 6 described in this section. An example of such a terrain is shown in Figure 25 where the two segments denoted 4 and 5 form the first wedge-shaped screen and the two segments denoted 8 and 9 form the second wedge-shaped screen. The remaining seven segments will be considered reflecting surfaces. Segments 1–3 form the surface on the source side of the first screen, segments 6–7 will form the surface between the screens while segments 10–11 form the surface on the receiver side of the second screen.
Figure 25
Example of a segmented terrain with one screen having one diffracting edge.

At this point it is assumed that the screen part of the terrain profile has already been identified and therefore that the number of segments before and after the screen which are considered reflecting segments are known. If the part of the input terrain forming the screen shape contains more than three ground points the screen shape is reduced to three points each as described in Section 5.21.

The screens are defined by the following point numbers in the terrain profile (numbered 1 to \( N_{ts} + 1 \) where \( N_{ts} \) is the number of segments in the terrain profile).

- \( iSCR,1 \) first screen, terrain point number closest to the source
- \( iSCR,12 \) first screen, terrain point number closest to the receiver
- \( iSCR,T1 \) first screen, terrain point number of the diffracting edge
- \( iSCR,21 \) second screen, terrain point number closest to the source
- \( iSCR,22 \) second screen, terrain point number closest to the receiver
- \( iSCR,T2 \) second screen, terrain point number of the diffracting edge

For the first screen, the line segment representing the wedge face closest to the source has the end coordinates \( W_{11} = (x_{SCR,11}, z_{SCR,11}) \) and \( T_1 = (x_{SCR,T1}, z_{SCR,T1}) \) while the line segment representing the wedge face closest to the receiver has the end coordinates \( W_{12} = (x_{SCR,12}, z_{SCR,12}) \) and \( T_1 = (x_{SCR,T1}, z_{SCR,T1}) \). Possible terrain points between point no.
iSCR,11 and iSCR,T1 and between point no. iSCR,12 and iSCR,T1 are ignored. In this case the flow resistivity $\sigma_{\text{SCR,T1-1}}$ and roughness $r_{\text{SCR,T1-1}}$ are used as representatives to the source side wedge face and $\sigma_{\text{SCR,T1}}$ and $r_{\text{SCR,T1}}$ are used as representatives to the receiver side wedge face.

For the second screen, the line segment representing the wedge face closest to the source has the end coordinates $W_{21} = (x_{\text{SCR,21}}, z_{\text{SCR,21}})$ and $T_2 = (x_{\text{SCR,T2}}, z_{\text{SCR,T2}})$ while the line segment representing the wedge face closest to the receiver has the end coordinates $W_{22} = (x_{\text{SCR,22}}, z_{\text{SCR,22}})$ and $T_2 = (x_{\text{SCR,T2}}, z_{\text{SCR,T2}})$. Possible terrain points between point no. iSCR,21 and iSCR,T2 and between point no. iSCR,22 and iSCR,T2 are ignored. In this case the flow resistivity $\sigma_{\text{SCR,T2-1}}$ and roughness $r_{\text{SCR,T2-1}}$ are used as representatives to the source side wedge face and $\sigma_{\text{SCR,T2}}$ and $r_{\text{SCR,T2}}$ are used as representatives to the receiver side wedge face.

The number of reflecting segments between the first screen will therefore be iSCR,11-1 numbered from $N_{s1} = 1$ to $N_{s2} = iSCR,11-1$, and the number of reflecting segments between the screens will therefore be iSCR,12-1 iSCR,21 numbered from $N_{m1} = iSCR,12$ to $N_{m2} = iSCR,21-1$ while the number of reflecting segments after the screen will be $N_{n1} + 1$-iSCR,22 numbered from $N_{r1} = iSCR,22$ to $N_{r2} = N_{n_1}$.

The base model will now used for all combinations of segments of the source side ($i_1 = N_{s1}$ to $N_{s2}$), source side ($i_2 = N_{m1}$ to $N_{m2}$) and on the receiver side ($i_3 = N_{r1}$ to $N_{r2}$). For each case of $i_1$, $i_2$ and $i_3$ the coordinates to use in the base model are:

- $T_1 = (x_{T1}, z_{T1}) = (x_{\text{SCR,T1}}, z_{\text{SCR,T1}})$
- $W_{11} = (x_{11}, z_{11}) = (x_{\text{SCR,11}}, z_{\text{SCR,11}})$
- $W_{12} = (x_{12}, z_{12}) = (x_{\text{SCR,12}}, z_{\text{SCR,12}})$
- $T_2 = (x_{T2}, z_{T2}) = (x_{\text{SCR,T2}}, z_{\text{SCR,T2}})$
- $W_{21} = (x_{21}, z_{21}) = (x_{\text{SCR,21}}, z_{\text{SCR,21}})$
- $W_{22} = (x_{22}, z_{22}) = (x_{\text{SCR,22}}, z_{\text{SCR,22}})$
- $Z_{s1} = Z_{\text{SCR,T1-1}}$
- $Z_{r1} = Z_{\text{SCR,T1}}$
- $Z_{s2} = Z_{\text{SCR,T2-1}}$
- $Z_{r2} = Z_{\text{SCR,T2}}$
- $P_{s1} = (x_{s1}, z_{s1}) = (x_{11}, z_{11})$
- $P_{s2} = (x_{s2}, z_{s2}) = (x_{i1+1}, z_{i1+1})$
- $Z_{G1} = Z_1$
- $w''(f) = w''(f)$
The base model is used to calculate the screen effect \( |p_{SCR}| \) and the ground effect \( |p_G| \). The former will be identical for all combinations of terrain segment and has to be calculated only once while the latter will vary for each combination of terrain terrain segments and will be denoted \( |p_{G,i_1,i_2,i_3}| \) for segment \( i_1, i_2 \) and \( i_3 \) on the source side of the screen, between the screens and on the receiver side, respectively.

Based on the sum of Fresnel-zone weights \( w''_{i_1}(f) = w''_{i_2}(f) = w''_{i_3}(f) \) on each side of the screens the Fresnel-zone weights are normalized as shown in Eqs. (268) and (270) and the weights \( w_{Q_1}, w_{Q_2} \) and \( w_{Q_3} \) used the base model are determined.

\[
\begin{align*}
    w_{i_1}(f) &= \sum_{i_2=N_{g_1}}^{N_{g_2}} w''_{i_1}(f) \\
    w_{i_2}(f) &= \sum_{i_3=N_{g_1}}^{N_{g_2}} w''_{i_2}(f) \\
    w_{i_3}(f) &= \sum_{i_2=N_{g_1}}^{N_{g_2}} w''_{i_3}(f) \\
    \Delta w_{i_1}(f) &= \begin{cases} 
        w_{i_1}(f) - 1 & \text{if } w_{i_1}(f) > 1 \\
        0 & \text{if } w_{i_1}(f) \leq 1 
    \end{cases} \\
    \Delta w_{i_2}(f) &= \begin{cases} 
        w_{i_2}(f) - 1 & \text{if } w_{i_2}(f) > 1 \\
        0 & \text{if } w_{i_2}(f) \leq 1 
    \end{cases} \\
    \Delta w_{i_3}(f) &= \begin{cases} 
        w_{i_3}(f) - 1 & \text{if } w_{i_3}(f) > 1 \\
        0 & \text{if } w_{i_3}(f) \leq 1 
    \end{cases} \\
    \Delta w_i(f) &= \Delta w_{i_1}(f) + \Delta w_{i_2}(f) + \Delta w_{i_3}(f)
\end{align*}
\]
Finally the sound pressure level $\Delta L_s$ of Sub-model 6 for a terrain with two screens is calculated according to Eq. (270).

$$
\Delta L_s = 20 \log \left( \left| \hat{p}_{SCR}(f) \prod_{i=i_1}^{N_{x1}} \prod_{j=j_1}^{N_{x1}} \prod_{k=k_1}^{N_{x1}} \hat{p}_{G,LJ,IJ} \left| w_i^*(f)w_j^*(f)w_k^*(f) \right| \right) \right) \tag{270}
$$

### 5.16 Sub-Model 7: Contribution from Turbulence Scattering behind Screens

The sound reduction of screens is limited by the energy scattered into the shadow zone of the screen from atmospheric turbulence. In the Nord2000 method the contribution of scattered energy in case of a non-refractive atmosphere depends on the distances $R_1$ and $R_2$ and the height $h_s$ measured relative to the source-receiver line as defined in Figure 26. The wind and temperature turbulences are described by the turbulence strengths $C_v^2$ and $C_T^2$. 
respectively. If the top of screen is below the source-receiver line the contribution from turbulent scattering is ignored.

![Diagram](image)

**Figure 26**
Definition of geometrical parameters for calculation of turbulent scattering in the shadow zone of a single edge screen.

In the Nord2000 work the original model was found to underestimate the contribution from turbulent scattering. Therefore, the effective turbulence strength parameters \( C_{ve}^2 \) and \( C_{Te}^2 \) were introduced as shown in Eq. (271).

\[
\begin{align*}
C_{ve}^2 &= 10C_v^2 \\
C_{Te}^2 &= 10C_t^2
\end{align*}
\]  

(271)

The sound pressure level contribution \( \Delta L_{ws} \) from wind turbulence relative to the free field level is given by Eq. (272) where \( f \) is the frequency, \( H \) is the auxiliary function defined in Section 5.23.8, and \( Coft \) the auxiliary function defined in Section 5.23.1. \( L_{ws0} \) is the normalized scattered sound pressure level from the wind turbulence disregarding the ground. \( L_{ws0} \) is determined by linear interpolation in the two-dimensional Table 6 with input parameters \( 40R_2/R_1 \) and \( 40h_e/R_1 \). Due to the lack of reciprocity in Table 6 the value \( L'_{ws0} = L_{ws0}(R_1,R_2,h_e) + 10 \log(R_f/40) \) is also calculated the case where source and receiver are interchanged and the maximum value is used as shown in Eq. (272). When the parameters are outside the values in the table, the nearest values of the parameters are used. \( C_{SR} \) is a correction which shall account for reflections in the ground surface before and after the screen and is the ground effect part of Eq. (188) limited downwards to a value of 1.
\[ L'_{w,t0} = \max \left( L_{w,t0}(R_1, R_2, h_x) + 10 \log \left( \frac{R_1}{40} \right), L_{w,t0}(R_2, R_1, h_x) + 10 \log \left( \frac{R_2}{40} \right) \right) \]

\[ \Delta L_{w,t} = L'_{w,t0} + 10 \log(C_{RS}) + \frac{10}{3} \log \left( \frac{f}{2000} \right) + 10 \log \left( C_{w}^2 \right) \]

\[ + 15H \left( f_0 - f \right) \log \left( \frac{f}{f_0} \right) + 15H \left( 0.5f_0 - f \right) \log \left( \frac{f}{0.5f_0} \right) \]

where

\[ \theta = \pi - \arctan \left( \frac{R_1}{h_x} \right) - \arctan \left( \frac{R_2}{h_x} \right) \]

\[ f_0 = \frac{C_{soft} (l_{mean})}{2 \sin \left( \frac{\theta}{2} \right)} \]

\[ C_{SR} = \begin{cases} P_G^2 & P_G > 1 \\ 1 & P_G \leq 1 \end{cases} \]

\[ P_G = \prod_{i=1}^{N_{a1}} \prod_{j=1}^{N_{a2}} \left| \hat{P}_{G,i,j,l} \right| v_{i,l}(f) v_{j,l}(f) \]

Table 7
Normalized scattered level $L_{s0}$ from temperature turbulence.

Finally, $\Delta L_{as}$ and $\Delta L_{ts}$ are added incoherently as shown in Eq. (274).

\[
\Delta L_f = 10 \log \left( 10^{\Delta L_{as}/10} + 10^{\Delta L_{ts}/10} \right)
\]  

(274)

In case of a refractive atmosphere the variables $R_1$, $R_2$ and $h_e$ are determined by Eq. (275) where $R_S$ and $R_R$ are defined in Eq. (161) while $\theta_1$, $\theta_2$, $\Delta \theta_S$, and $\Delta \theta_R$ are defined in Eq. (162).
If two screens are included (Sub-model 5 and 6) the parameters \( R_1 \), \( R_2 \) and \( h_e \) are determined for an equivalent single screen top \( T \) as shown in Figure 27 where \( T_1 \) and \( T_2 \) are the two screen edges (may be two screens or one screen with two edges). The point \( T \) can be determined as described below. \( C_{SR} \) is in this case approximated by the ground effect part of the double edge effect screen effect \( p_G \). (gå i detaljer med dette når sub-model 6 er beskrevet).

Firstly, the parameters are calculated for \( T_1 \) and \( T_2 \) in Eq. (276)

\[
\begin{align*}
x'_S &= x_T - R_S \sin(\theta_1 + \Delta \theta_S) \\
z'_S &= z_T - R_S \cos(\theta_1 + \Delta \theta_S) \\
x'_R &= x_T + R_K \sin(\theta_2 + \Delta \theta_R) \\
z'_R &= z_T - R_K \cos(\theta_2 + \Delta \theta_R) \\
(x'_T, z'_T, h_e) &= \text{NormLine}(x'_S, z'_S, x'_R, z'_R, x_T, z_T) \\
R_1 &= \text{Length}(x'_S, z'_S, x'_T, z'_T) \\
R_2 &= \text{Length}(x'_R, z'_R, x'_T, z'_T) \\
\end{align*}
\]

The parameters corresponding to the equivalent screen top can now be determined by Eq. (393).
In the combined model described in Section 5.21.6 the Sub-model 7 is referred to as Sub-model 7,1 in the one edge case and Sub-model 7,2 in the two edge case.

5.17 Sub-Model 8: Multiple Ground Reflections

In the Sub-models 1 to 6 described above the number of rays in the models are fixed even in case of strong downward refraction. In case of strong downward refraction and long propagation distances rays may be reflected by the ground more than once on the way to the receiver. This phenomenon is called multiple ground reflections. If multiple ground reflections occur the number of rays will increase beyond the number which is included in submodel 1 to 6.

The purpose of Sub-model 8 is to calculate the contribution to the sound levels from rays not included in submodel 1 to 6.

The method used in the present sub-model has been developed for a logarithmic sound speed profile as shown in Eq. (278) and for propagation over flat terrain.

\[ c(z) = A \ln \left( \frac{z}{z_0} + 1 \right) + C \tag{278} \]

The first step is to determine the approximate number of rays \( N \) (decimal number) by Eq. (279) where \( d \) is the horizontal propagation distance, \( h_{\text{max}} \) is the maximum value of the source height \( h_S \) and the receiver height \( h_R \) and \( A \) and \( C \) are the weather coefficients in Eq. (278).

\[ N = \frac{4d_{\text{base}}}{h_{\text{max}}} \sqrt{\frac{A}{2\pi C}} \]

where

\[ h_{\text{max}} = \text{Max}(h_S, h_R) \tag{279} \]

For a value of \( N \) less than 4 the contribution from additional rays are ignored whereas the contribution will be calculated as described in the following for values of \( N \) greater than 4.
The number $N$ is divided in an integer part $N_i$ ($N$ is rounded down) and a fractional part $\Delta N$ as shown in Eq. (280).

$$N = N_i + \Delta N \quad (280)$$

Reflected rays are categorised by different orders, where the order $n$ is the number of reflections of a specific ray. The order $n$ for ray number $M$ is determined as shown in Eq. (281) which also defines the maximum order $n_{\text{max}}$. The function $\text{Int}$ is a function which returns the integer part of the argument.

$$n = \text{Int}\left( \frac{M - 1}{4} \right) + 1 \quad (281)$$

$$n_{\text{max}} = \text{Int}\left( \frac{N - 1}{4} \right) + 1$$

The contribution $\Delta L_{\text{multi}}$ from multiple reflections is calculated according to Eq. (282). The equation contains two solutions $\Delta L_{\text{multi},hf}$ and $\Delta L_{\text{multi},lf}$ which shall be used at high and low frequencies, respectively. $R(n)$ is the reflection coefficient and $A_{\text{ray}}(n)$ is the ray tube area for a ray of order $n$. The high frequency solution corresponds to uncorrelated summation of the ray contributions and the low frequency solution to correlated summation. Reference [2] contains a discussion of the transition between the two solutions but a safe principle was not found within the Nord2000 project. For normal purposes where the medium and high frequency range determines the $A$-weighted sound pressure level it is recommended to apply the high frequency solution. However, in cases where low frequency propagation is important the low frequency solution giving higher values of $\Delta L_{\text{multi}}$ should be used instead.

$$\Delta L_{\text{multi},hf} = 10\log \left( (\Delta N \cdot R(n_{\text{max}})^{n_{\text{max}}} \cdot A_{\text{ray}}(n_{\text{max}}))^2 + \sum_{M=5}^{N} (R(n)^n \cdot A_{\text{ray}}(n))^2 \right)$$

$$\Delta L_{\text{multi},lf} = 20\log \left( (\Delta N \cdot R(n_{\text{max}})^{n_{\text{max}}} \cdot A_{\text{ray}}(n_{\text{max}}))^2 + \sum_{M=5}^{N} (R(n)^n \cdot A_{\text{ray}}(n))^2 \right) \quad (282)$$

The values $R(n)$ and $A_{\text{ray}}(n)$ are determined as shown in Eq. (283). $d_{\text{segm}}(i)$ is defined in Section 5.4.1, $\rho_{\text{ray}} = 0.00001$ and $c(z)$ is determined by Eq. (278).
\[ R(n) = \sum_{i=1}^{N} \left| \hat{R}_h(f, \psi_G(n), \hat{Z}_G(f)) \right| \frac{x_{i+1} - x_i}{x_{SGv} - x_{SGv}} \]

\[ A_{ray}(n) = 10^{-0.1} \sqrt{\frac{\psi_G(n) - \psi'_G(n)}{\rho_{ray} \sin \psi_G(n)}} \]

where

\[ h_{max}(n) = \frac{d_{base}}{n} \sqrt{\frac{A}{2\pi C}} \]

\[ \psi_G(n) = \arccos \left( \frac{C}{c(h_{max}(n))} \right) \]

\[ \psi'_G(n) = \arccos \left( \frac{C}{c\left(1 + \rho_{ray} h_{max}(n)\right)} \right) \]

The method described above is valid for propagation over flat terrain with a logarithmic sound speed profile defined by the weather coefficients A and C. In the general case where the vertical sound speed profile also may contain a linear part defined by the weather coefficient B as shown Eq. (2) and where the terrain may be non-flat, some interpretation is needed before the method can be applied.

In the case where the weather coefficient B is not zero, the combined refraction of the logarithmic and linear profile calculated by auxiliary function RayCurvature and expressed by the radius of curvature \( R_{A,B} \) as shown in Eq. (284). The value \( A' \) in a purely logarithmic sound speed profile giving the same value of \( R_{A,B} \) are determined by Eq. (284) and used in Eq. (278).

\[ \left( R_{A,B}, NA \right) = RayCurvature(A, B, C, d, h_s, h_R) \]

\[ A' = \frac{\pi C d^2}{32 R_{A,B}^2} \]

(284)

If the terrain is flat with screens, \( h_{max} \) in Eq. (279) is determined by the maximum value of the source, receiver and screen heights.

If the terrain is non-flat, the heights of source, receiver and screens are determined relative to the terrain baseline and \( h_{max} \) is defined as the maximum value of these heights. If the average deviation of the terrain from the terrain baseline is less than 0 (meaning that the terrain on average is lower than the baseline indicating a valley shaped terrain), \( h_{max} \) is modified by adding the numerical value of the deviation. This is expressed in Eq. (285). \( h_{base}(i) \) and \( d_{segm}(i) \) are defined in Section 5.4.1.
\[ h_{\text{max}} = \text{Max}(h_S, h_R, h_{\text{base,m}}, h_S - h_{\text{base}}, h_R - h_{\text{base}}, h_{\text{base,m}} - h_{\text{base}}) \]

where
\[ h_{\text{base,m}} = \text{Max}(h_{\text{base}}(i)) \quad i = 2,3,...,N_t \]
\[ \bar{h}_{\text{base}} = \frac{\sum_{i=1}^{N_t} h_{\text{base}}(i+1) - h_{\text{base}}(i)}{2} \frac{x_{i+1} - x_i}{x_{\text{RGv}} - x_{\text{SGv}}} \]  

5.18 Sub-Model 9: Air Absorption

The propagation effect of air absorption is calculated on the basis of ISO 9613-1 which predicts pure-tone attenuation in one third octave bands. The prediction according to ISO is based on the frequency \( f \), the air temperature \( t_{\text{air}} \) (°C), the relative humidity \( \text{RH} \) (%), and the atmospheric pressure \( p_{\text{rel}} = p_r/p_0 \) relative to the reference atmospheric pressure (atm). The attenuation \( \alpha \) in dB/m at the frequency \( f \) in dB is calculated by Eq. (286).

\[ T_0 = 293.15 \]
\[ T_{01} = 273.16 \]
\[ T = t_{\text{air}} + 273.15 \]
\[ h = \frac{\text{RH}}{p_{\text{rel}}} \left( \frac{T}{T_0} \right)^{1.221} + 4.615 \]
\[ f_{rO} = p_{\text{rel}} \left( 24 + 40400h \frac{h + 0.02}{h + 0.391} \right) \]
\[ f_{rN} = p_{\text{rel}} \left( \frac{T}{T_0} \right)^{1/2} \left( 9 + 280h \exp \left( -4.170 \left( \frac{T}{T_0} \right)^{1/3} - 1 \right) \right) \]
\[ \times \left( \frac{1.84 \times 10^{-11} \left( \frac{T}{T_0} \right)^{1/2} + \left( \frac{T}{T_0} \right)^{-5/2}}{p_{\text{rel}}} \right) \]
\[ \alpha(f) = 8.686 f^2 \left( \frac{0.01275 \exp \left( \frac{-2239.1}{T} \right)}{f_{rO} + \frac{f^2}{f_{rO}}} + \frac{0.1068 \exp \left( \frac{-3352}{T} \right)}{f_{rN} + \frac{f^2}{f_{rN}}} \right) \]

The propagation effect of air absorption \( \Delta L_a \) for each one-third octave band can now be determined by Eq. (287) where \( A_0 \) is the one-third octave band air attenuation for centre frequency \( f_0 \) and propagation path length \( R \).
\[ A_0 = \alpha(f_0)R \]
\[ \Delta L_{\alpha} = -A_0 \left(1.0053255 - 0.00122622 A_0\right)^{0.6} \]  

(287)

5.19 Sub-Model 10: Scattering Zones

A scattering zone is an area which contains so many interfering objects that almost all direct sound from source to receiver is blocked. Instead, the sound arrives at the receiver after a large number of reflections and diffractions. In such cases the complex propagation is described using statistical approaches (statistical scattering methods).

The Nordtest method ([1] and [2]) contains solutions for housing areas and forests but in the Nordtest method it has been decided only to apply the method for forests. The reason is that most computer programs is handling propagation in housing areas by directly including all ray paths reflected by buildings. The method is therefore not likely to be used in housing areas at the same time as the calculation accuracy is not well known. The Nord2000 method [1] also includes a method for combining varying types of scattering zones (mixed housing areas and forests and varying scattering zone variable. This has also been omitted from the Nordtest method.

According to Eq. (1) the propagation effect of terrain \( \Delta L_t \) and scattering zones \( \Delta L_s \) shall be calculated separately. However, the calculation of \( \Delta L_t \) may be affected by the existence of a scattering zone giving a reduction in coherence coefficients.

In prediction of scattering zone propagation effects one of the fundamental parameters is the sound path length \( R_{sc} \) in the scattering volume as shown in Figure 28 and Figure 29. When the source-receiver is not blocked by obstacles (in excess of the scattering zones), \( R_{sc} \) is measured along the source-receiver sound path as shown in Figure 28. When the source-receiver is blocked, \( R_{sc} \) is measured along the sound path over the top of the obstacles using the “rubber band” principle shown in Figure 29. When a screen inside a scattering zone cannot be considered a natural part of the scattering zone (e.g. a house in a forest or a very large building inside a low housing area) the screen is taken into account in the calculation of \( \Delta L_t \) and ignored in the calculation of \( \Delta L_s \). Therefore such a screen is taken into account when defining the sound path used to determine \( R_{sc} \).

![Figure 28](image-url)
Propagation path used to determine the scattering zone path length $R_{sc}$ when the line of sight is unblocked by terrain or screens.

Figure 29
Propagation path used to determine the scattering zone path length $R_{sc}$ when the line-of-sight is blocked by terrain or screens.

The coherence coefficient $F_s$ corresponding to scattering to be used when calculating the terrain effect $\Delta L_t$ is determined by Eq. (288).

$$F_s = 1 - k_f T$$  \hspace{1cm} \text{(288)}$$

The variable $T$ in Eq. (288) is calculated by Eq. (289) where $nQ$ is given by Eq. (290). $R_{sc}$ is the total sound path length of the scattering zones ($R_{sc} = \Sigma R_{sc,i}$ where $R_{sc,i}$ is the sound path length of the i’th scattering zone).

$$T = \text{Min} \left( \frac{R_{sc} nQ}{1.75} \right)$$  \hspace{1cm} \text{(289)}$$

$k_f$ is determined by Table 8. The parameter $ka$ is the product of the wave number $k$ and the mean stem radius $a$. Linear interpolation is used to determine $k_f$ for other values of $ka$ than those shown in the table.

Table 8

Frequency weighting function \(k_f\) for forests as a function of \(ka\) where \(k\) is the wave number and \(a\) is the mean stem radius.

In case of forests (or other dense vegetation) \(nQ\) is determined by Eq. (290) where \(n''\) is the density of trees (m\(^{-2}\)) and \(a\) is the mean stem radius (m).

\[
nQ = 2an''
\]  

(290)

The propagation effect of the scattering zone \(\Delta L_s\) is calculated by Eq. (291) where \(k_f\) and \(T\) are as defined above. \(A_s(R_{sc})\) is a level correction due to scattering. \(\Delta L_s\) has been limited downwards to a value of -15 dB.

\[
\Delta L_{s0} = \text{Max}(1.25k_f/TA_s(R_{sc})) - 15
\]

where

\[
A_s(R_{sc}) = \Delta L(h', \alpha, R') + 20\log(8R')
\]  

(291)

In Eq. (291) \(h'\) is the normalised scatter obstacle height defined by \(h' = nQh\) where \(h\) is the average scatter obstacle height. \(\alpha\) is the absorption coefficient of the scatter obstacles (normally in the range 0.1 - 0.4). \(R'\) is the normalised effective distance through the scattering zone defined by \(R' = nQR_{sc}\). \(\Delta L(h', \alpha, R')\) is determined from the three-dimensional Table 9 with parameters \(h', \alpha, \) and \(R'\) using cubic interpolation.

</table>
Table 9
Table for determining $\Delta L(h', \alpha, R')$ for a scattering zone.

In the scattering zone method described above it is assumed that the height of the scattering zone is sufficiently large. In cases with a limited height of the scattering zone this may not be fulfilled. If the scattering zone is below the sound ray any effect is automatically ignored as $R_{sc}$ will be zero. However, if the upper end of the scattering zone is just above the sound ray it is possible to have a sudden considerable change in $R_{sc}$ and therefore a large discontinuity. To avoid this, a transition principle has been developed which will be described in the following. In the transition principle a smooth transition is obtained from the case where no effect is assumed when the scattering zone is below the sound ray to the case where the full effect is obtained when the scattering zone is sufficiently high.

In the transition principle the volume of the scattering zone within the half of the Fresnel ellipsoid above the sound ray relative to the entire volume of this half Fresnel ellipsoid is used to modify the $R_{sc}$ as shown in Figure 30. In case of refraction the ray path from $S$ to $R$ is an arc of a circle and the Fresnel ellipsoid is bended along the ray path. However, as the approach is very approximate the calculation of the volumes is simplified.

In the transition principle the volume of the scattering zone within the half of the Fresnel ellipsoid above the sound ray relative to the entire volume of this half Fresnel ellipsoid is used to modify the $R_{sc}$ as shown in Figure 30. In case of refraction the ray path from $S$ to $R$ is an arc of a circle and the Fresnel ellipsoid is bended along the ray path. However, as the approach is very approximate the calculation of the volumes is simplified.

**Figure 30**
Limited height of the scattering zone within half of the Fresnel ellipsoid above the sound ray in case of a non-refractive atmosphere.

The height of the sound ray $z_{ray}(x)$ and the ray path lengths $R_1(x)$ and $R_2(x)$ to the source and receiver, respectively, are determined by Eq. (292).

$$
\begin{align*}
\left(NA, \xi_{ray}\right) &= RayCurvature(A, B, C, x_R - x_S, h_S, h_R) \\
\left(z_{ray}(x), R_1(x), R_2(x)\right) &= HeightOfCircularRay(x_R - x_S, h_S, h_R, \xi_{ray}, x - x_S)
\end{align*}
$$

(292)

The intersection between the $y$-plane and the Fresnel ellipsoid which is an ellipse is replaced by the circumscribed rectangle with height and width to each side of the sound ray...
of $r_{Fz}(x)$ as shown in Figure 31. $r_{Fz}(x)$ is half the width of Fresnel ellipsoid at $x$ calculated according to Eq. (293) using the auxiliary function $CalcFZd$. $\lambda$ is the wavelength and the calculation is based on a fraction $F_\lambda = 1/8$.

$$r_{Fz}(x) = CalcFZd \left( R_1(x), R_2(x), \frac{\pi}{2}, \lambda/8 \right)$$

(293)

Now the modified value $R'_sc$ can be determined by Eq. (294) based on the volume of the simplified Fresnel-shape $V_{Fz}$ and the scattering volume $V_{sc}$ inside the shape. $x_1$ and $x_2$ is the start and end coordinate of the intersection between the sound ray and the scattering belt. If there is more than one scattering zone along the propagation path only values of $x$ inside the scattering zones are included in the integration in Eq. (294). The modified value $R'_sc$ is used instead of $R_{sc}$ in the method described above. The integrals are solved approximately using the trapezoidal rule after having divided the volume in vertical strips in the $x$- as well as the $y$-direction. The maximum width of the strips depends on the shape of volume but a simple approach is to use 100 strips placed equidistantly in the two directions which is assumed to be sufficiently accurate for all practical cases.
\[ R'_{sc} = R_{sc} \frac{V_{sc}}{V_{Fc}} \]

where

\[ V_{Fc} = \int_{x=x_1}^{x_2} 2r_{sc}^2(x)dx \]

\[ V_{sc} = \int_{x=x_1}^{x_2} \left( \int_{y=r_{sc}(x)}^{r_{sc}(x)} \Delta z_{sc}(x, y)dy \right)dx \]

\[ \Delta z_{sc}(x, y) = \begin{cases} 
0 & z_{sc}(x, y) \leq z_{ray}(x) \\
- z_{ray}(x) & z_{ray}(x) < z_{sc}(x, y) < z_{ray}(x) + r_{sc}(x) \\
r_{sc}(x) & z_{sc}(x, y) \geq z_{ray}(x) + r_{sc}(x) 
\end{cases} \]

5.20 Sub-Model 11: Reflection Effect

Sound reflected from an obstacle such as a building facade or a noise screen is dealt with by introducing a reflection path from the source \( S \) via the reflection point \( O \) to the receiver \( R \) as shown in Figure 1 in Section 5.3.4 where the input variables used in Sub-model 11 are defined. The reflection point is at the intersection between the straight line from the image source \( S' \) to the receiver \( R \) and the plane which contains the reflecting surface. Therefore, the reflection point may be outside the real surface.

The propagation effect of the reflection path is predicted by the same propagation model used for the direct path on basis of the propagation parameters determined along the reflection path. However, the propagation effects in Eq. (1) also include a propagation effect \( \Delta L_r \) which is a correction for the efficiency of the reflection.

As the direction of propagation is changing at the reflection point \( O \), the weather coefficients \( A \) and \( B \) in Eq. (2) may also change at the reflection point due to the wind effects. Based on the input variables defined in Section 5.3.4 \( A \) and \( B \) are determined by Eq. (295). This principle can easily be extended to more than one reflection in which case the varying values of \( A \) and \( B \) for each part of the reflection path are weighted by its length \( d \).

\[ A = \frac{d_1A_1 + d_2A_2}{d_1 + d_2} \]
\[ B = \frac{d_1B_1 + d_2B_2}{d_1 + d_2} \]  

(295)

The correction \( \Delta L_r \) depends on the size of the reflector and reflection coefficient of the reflecting surface as shown in Eq. (296). The first term in the equation is a correction for the effective energy reflection coefficient \( \rho_E \) and the second term is a correction for the “effec-
tive" size of the reflecting surface. If the reflector placed over a terrain surface the “effective” size is the combination of the reflector itself and the image of the reflector in the terrain surface. \( S_{\text{refl}} \) is the area of the “effective” surface within the Fresnel-zone in the plane of reflection and \( S_{Fz} \) is the total area of the Fresnel-zone. \( S_{\text{refl}} \) is determined on basis of the input variables \( z_{r,upp}, z_{r,low}, d_{r,l}, \) and \( d_{r,r} \) defined in Section 5.3.4. In order to avoid unnecessary calculation of \( S_{\text{refl}} \) and \( S_{Fz} \) a reflecting surface is ignored if the point of reflection is more than 2 m outside one of the surface edges.

\[
\Delta L_{11} = 10 \log(\rho_E(f)) + 20 \log \left( \frac{S_{\text{refl}}(f)}{S_{Fz}(f)} \right)
\]

(296)

For a reflecting surface with a frequency dependent absorption coefficient \( \alpha \) the energy reflection coefficient \( \rho_E \) is calculated by Eq. (297).

\[
\rho_E(f) = 1 - \alpha(f)
\]

(297)

In order to calculate \( S_{Fz} \) and \( S_{\text{refl}} \) the position of the Fresnel-zone around the reflection point \( O = (x_O, z_O) \) has to be determined (\( x_O = d_l \)). If the reflector is vertical (the method is applicable also for non-vertical reflectors but a description has not been included in the present Nordtest standard due to the substantial complexity of the geometrical calculations) The coordinate \( x_O \) is easily determined by the intersection between the line \( S'R \) and the reflector as shown in Figure 1. The coordinate \( z_O \) is more difficult to calculate as the ray path is circular but can be determined on basis of Eq. (298) giving the height \( h_{O,\text{base}} \) of \( O \) above the terrain baseline. \( R_1 \) and \( R_2 \) are lengths of the ray path from \( O \) to \( S \) and \( R \), respectively, as defined in Figure 32.

\[
\begin{align*}
(NA, \xi_{ray}) &= \text{RayCurvature}(A, B, C, d, h_s, h_R) \\
(h_{O,\text{base}}, R_1, R_2) &= \text{HeightOfCircularRay}(d, h_s, h_R, \xi_{ray}, d_1)
\end{align*}
\]

(298)

The dimension \( d_{\text{FZ}}(f) \) of the Fresnel-zone above, below, left or right of \( O \) can be determined by Eq. (299) where \( \theta_r \) is the angle between the ray path at \( O \) and the direction to the Fresnel-zone border under consideration, \( F_{\lambda} = 1/8 \), and \( \lambda \) is the wavelength.

\[
d_{\text{FZ}}(f) = \text{CalcFZd}(R_1, R_2, \theta_r, F_{\lambda}, \lambda)
\]

(299)

As mentioned in Section 5.8 the Fresnel zone is in the Nord2000 method geometrically simplified by using the circumscribed rectangle symmetrically placed around the major axis of the Fresnel ellipse. If \( d \gg h_s + h_R \) which most often is fulfilled at the same time as the reflector is assumed to be vertical, the two axes of the ellipse can be assumed to be horizontal and vertical which simplifies the geometrical calculations.
A difference in directivity between the direct and reflected sound path is assumed to be incorporated in $L_W$ in Eq. (1).

The reflected sound is added incoherently to the direct sound.

Irregularly shaped obstacles may be divided into a number of sub-surfaces which each fulfils the requirement of being a plane surface, and the overall effect is obtained by a simple incoherent summation of the contributions from all surfaces.

### 5.21 Interpretation of Terrain

Before the sound pressure level can be determined by the combined model described in Section 5.21.6 the terrain must be characterized as one of the following sub-models:

1. Flat terrain with one type of surface
2. Flat terrain with more than one type of surface
3. Non-flat terrain without screens
4. Terrain with one screen having one edge
5. Terrain with one screen having two edges

6. Terrain with two screens

The result may also be a combination of the six sub-models where the calculation is carried by two or more sub-models and where the final results is obtained by interpolation between the sub-model results.

In the following models will be mentioned which are a combination of the sub-models shown above. These are:

- The “Flat” model with the propagation effect $\Delta L_{\text{flat}}$ is either the model for flat terrain with one type of surface or with more than one type of surface (Sub-models 1 or 2).
- The “NoScreen” model with the propagation effect $\Delta L_{\text{noScr}}$ is a combination of the “Non-flat terrain without screens” model (Sub-model 3) and the “Flat terrain” model.
- The “OneScreen” model with the propagation effect $\Delta L_{\text{scr1}}$ may be a combination of the two one screen models (Sub-models 4 and 5).
- The “Screen” model with the propagation effect $\Delta L_{\text{scr}}$ may be a combination of the three screen models (Sub-models 4, 5, and 6).

The first step will therefore be to make an interpretation of the terrain to determine if a part of the terrain is a screen. If so, the most efficient screen is found (is denoted the primary screen in the method). If the terrain contains more than one screen, the second most efficient screen is then found (is denoted the secondary screen in the method). Screens other than the two most efficient screens are ignored and the terrain segments forming these screens are considered simple ground reflection segments. If the screen shape of the primary and secondary screen has more than one edge it is determined which edge is the most efficient edge. If only one screen has been found it is investigated if the screen shape has more than one efficient edge. Such an edge will be denoted the secondary edge. Finally the primary screen shape and a possible secondary screen will be simplified to include only the primary edge and a possible secondary edge in the primary screen.

### 5.21.1 Determination of a Primary Edge of a Primary Screen

The presence of a screen in the terrain profile is only possible if the number of terrain segment $N_{ts}$ ($=\text{nxz}-1$) exceeds one. If this is the case, the procedure described in the following is used for determining the most efficient edge of the primary screen.

Each point in the terrain except the first and last point and points at or below the terrain baseline ($h_{\text{base}}(i) \leq 0$ where $i$ is the number of the point) are considered a potential diffraction point. To determine the most efficient diffraction point the path length difference $\Delta \ell_0$ for a non-reacting atmosphere is calculated by Eq. (300) where the terrain point considered is $P_i = (x_i, z_i)$ and $z_m$ is the height of the line of sight $\text{SR}$ at $x_i$. The use of the auxiliary func-
tion $H(x)$ will cause $\Delta \ell$ to be greater than zero if $P_i$ is above the line $SR \ (z_i - z_m > 0)$ and less than zero if $P_i$ is below the line.

$$\Delta \ell_0 = H(z_i - z_m) \left| SP_i \right| + \left| RP_i \right| - \left| SR \right|$$

where

$$z_m = \left( z_R - z_S \right) \frac{x_i - x_S}{x_R - x_S} + z_S$$

The point no. $i$ with the largest value of $\Delta \ell_0$ will be defined as the most efficient edge of the primary screen. Later in the procedure this edge may turn out to be inefficient in which case the screen is ignored. The point is denoted $T_1 = (x_{T1}, z_{T1})$.

When $T_1$ has been determined, the next step will be to determine the efficiency of the diffraction point. This is done by calculating a transition parameter denoted $r_{scr1}$. This parameter will be determined on basis of the path length difference $\Delta \ell$ including the effect of refraction and on the distance $h_{base,T1}$ of $T_1$ to the terrain baseline.

$$\Delta \ell = \text{Sign}(\theta_S - \theta_R - \pi) \sqrt{R_S^2 + R_R^2 - 2 R_S R_R \cos(\theta_S - \theta_R)} - R_S - R_R$$

The efficiency of the diffraction point $T_1$ is determined based on three criterions:

1) $\Delta \ell'$ shall be sufficiently large where $\Delta \ell' = \max(\Delta \ell, \Delta \ell_0)$

2) The height of the screen above the ground surface shall be sufficiently large compared to the wavelength

3) The height of the screen above the ground surface shall be sufficiently large compared to the effective width of the sound field at the screen

The first criterion is based on an interpolation parameter $r_M(\lambda)$ determined according to Eq. (302). A value of $r_M$ equal to 1 indicates full screening effect and 0 indicates insignificant screening effect. $r_M$ is a function of the wavelength $\lambda$. 
The second criterion is based on an interpolation parameter \( r_\lambda(\lambda) \) determined according to Eq. (303). A value of \( r_\lambda \) equal to 0 and 1 indicates no screening and full screening, respectively. \( h_{SCR} = h_{base}(i_{T1}) \) is the perpendicular distance from \( P_{T1} \) to the terrain baseline.

\[
r_\lambda(\lambda) = \begin{cases} 
1 & \frac{\Delta \lambda'}{\lambda} \geq 0 \\
1 - \sqrt{7.5 \frac{\Delta \lambda'}{\lambda}} & -0.133 < \frac{\Delta \lambda'}{\lambda} < 0 \\
0 & \frac{\Delta \lambda'}{\lambda} \leq -0.133 
\end{cases}
\] (302)

The third criterion is based on an interpolation parameter \( r_{Fz}(\lambda) \) determined according to Eq. (304). A value of \( r_{Fz} \) equal to 0 and 1 indicates no screening and full screening, respectively. \( h_{SCR} \) is defined in the same way as in Eq. (337) and the effective width of the sound field is quantified by half the width of the Fresnel-zone \( h_{Fz}(f) \) determined by the auxiliary function \( CalcFZd \) using a fraction of the wavelength \( F_{\lambda} = 0.5 \).

\[
r_{Fz}(\lambda) = \begin{cases} 
1 & \frac{h_{SCR}}{h_{Fz}} \geq 0.3 \\
\frac{h_{SCR}/\lambda - 0.1}{0.2} & 0.1 < \frac{h_{SCR}}{h_{Fz}} < 0.3 \\
0 & \frac{h_{SCR}}{h_{Fz}} \leq 0.1 
\end{cases}
\] (303)

\[
where \quad h_{Fz}(\lambda) = CalcFZd(d_{base}(i_{T1}), d_{base} - d_{base}(i_{T1}), \pi/2, 0.5\lambda)
\]

The three transition parameters are finally combined into the screen transition parameter \( r_{scr}(f) \) calculated by Eq. (339).

\[
r_{scr}(f) = r_{\nu}(f) r_{\lambda}(f) r_{Fz}(f)
\] (305)
For screens below the line-of-sight the parameter $r_{3\ell}$ will reduce the efficiency of a screen at high frequencies whereas $r_1$ and $r_{Fz}$ will reduce the efficiency at low frequencies.

The purpose of transition parameter $r_{scr}$ is used to combine the “NoScreen” model and the “Screen” model as shown in Eq. (340).

$$\Delta L(f) = r_{scr}(f)\Delta L_{scr}(f) + (1 - r_{scr}(f))\Delta L_{noscr}(f)$$

(306)

If $r_{scr}(f)$ is greater than zero at at least one frequency it will be necessary to make calculations by the “Screen” model. In this case it will be necessary to define which part of the terrain shall be interpreted as the “screen shape”. The start of the screen is defined as the non-convex point closest to $T_1$ on the source side of $T_1$ and the end of the screen is defined as the non-convex point closest to $T_1$ on the receiver side of $T_1$. Whether a point is convex or non-convex is determined by the auxiliary function $Convex(i)$. The start point of the screen is denoted $W_1$ and the end point $W_2$.

5.21.2 Determination of a Primary Edge of a Secondary Screen

If a primary screen was found in Section 5.21.1 and $r_{scr}(f)$ is greater than zero at at least one frequency the next step will be to search for a secondary screen.

Each point in the terrain except the first and last point, the points being a part of the primary screen shape, and points at or below the terrain baseline ($h_{base}(i) \leq 0$ where $i$ is the number of the point) the point is considered a potential diffraction point in the secondary screen. To determine the most efficient diffraction point the path length difference $\Delta \ell$ has to be determined by a procedure slightly modified compared to the procedure used for the primary screen.

If $\Delta \ell$ calculated in Section 5.21.1 for the primary edge of the primary screen is less than zero $T_1$ is below the line SR. In this case the first step will be to determine the point $T_1' = (x_{T1}, z_{T1'})$ on the line SR vertically above $T_1$ as shown in Fig. 24.
The procedure is now to determine the path length difference $\Delta l_0$ on the source and on receiver side of the screen. This is done using a procedure similar to the one described in Section 5.21.1 where $\Delta l_0$ is calculated according Eq. (300). However, when calculating the maximum value of $\Delta l_0$ on the source side the point R is replaced by $T_1$ or $T_1'$ if $T_1$ is below the line SR. In the same way, when calculating the maximum value of $\Delta l_0$ on the receiver side of the screen the point S is replaced by $T_1$ or $T_1'$ if $T_1$ is below the line SR.

The point giving the maximum value of $\Delta l_0$ is defined as the primary diffracting edge of the secondary screen and is denoted $T_2 = (x_{T2}, z_{T2})$.

When $T_2$ has been determined, the next step is to determine the efficiency of the diffraction point. This is done by calculating a transition parameter denoted $r_{SCR2}$. This parameter will be determined on basis of the path length difference $\Delta \ell$ including the effect of refraction and on the distance $h_{base}(T_2)$ of $T_2$ to the terrain baseline.

$\Delta \ell$ is calculated by Eq. (307) where $R'_S$ and $R'_R$ are ray path length determined on basis of $R_S, R_M, R_R$ in Eq. (226) and $\theta'_S$ and $\theta'_R$ are the diffraction angles determined on basis of $\theta_{1S}$ and $\theta_{1R}$ in Eq. (227) and $\theta_{2S}$ and $\theta_{2R}$ in Eq. (228). If the secondary screen is the screen closest to the receiver $R'_S = R_M, R'_R = R_R, \theta'_S = \theta_{2S}$ og $\theta'_R = \theta_{2R}$. If the secondary screen is the screen closest to the source $R'_S = R_S, R'_R = R_M, \theta'_S = \theta_{1S}$ og $\theta'_R = \theta_{1R}$.

$$\Delta \ell = \text{Sign}(\theta'_S - \theta'_R - \pi) \sqrt{R'_S^2 + R'_R^2 - 2R'_S R'_R \cos(\theta'_S - \theta'_R)} - R'_S - R'_R$$  (307)
The efficiency of the diffraction point $T_2$ is based on the three criterions described in Section 5.21.1 and a fourth criterion saying that the distance between $T_1$ and $T_2$ shall be sufficiently large compared to the wavelength. The interpolation parameters $r_{\Delta T}(\lambda)$, $r_\ell(\lambda)$, and $r_{F_2}(\lambda)$ corresponding to the three criterions are calculated by Eqs. (302) through (304) in the same way as for the primary edge of the primary screen but for $T_2$ instead of $T_1$. The interpolation parameters are in this case denoted $r_{\Delta T_2}(\lambda)$, $r_{T_2}(\lambda)$, and $r_{F_{2T}}(\lambda)$, respectively.

The interpolation parameter $r_w(\lambda)$ corresponding to the fourth criterion is determined by Eq. (308).

$$r_w(\lambda) = \begin{cases} 1 & d_{12} \geq \lambda \\ \frac{d_{12}/\lambda - 0.3}{0.7} & 0.3\lambda < d_{12} < \lambda \\ 0 & d_{12} \leq 0.3\lambda \end{cases}$$

(308)

where

$$d_{12} = Length(x_{T_1}, z_{T_1}, x_{T_2}, z_{T_2})$$

The four interpolation parameters are finally combined into the transition parameter of the secondary screen $r_{scr2}(f)$ calculated by Eq. (309).

$$r_{scr2}(f) = r_{\Delta T_2}(f) r_{T_2}(f) r_{F_{2T}}(f) r_w(f)$$

(309)

The purpose of transition parameter $r_{scr2}$ is to combine the result of Sub-model 6 (terrain with screens) and the result by the “OneScreen” model (Sub-model 4 or a combination of Sub-model 4 and 5) as shown in Eq. (310).

$$\Delta L_{scr}(f) = r_{scr2}(f)\Delta L_q(f) + (1 - r_{scr2}(f))\Delta L_{scr1}(f)$$

(310)

If $r_{scr2}(f)$ is greater than zero at at least one frequency it will be necessary to make calculations by Sub-model 6. In this case it will be necessary to define which part of the terrain shall be interpreted as the “secondary screen shape”. The start of the screen is defined as the non-convex point closest to $T_2$ on the source side of $T_2$ and the end of the screen is defined as the non-convex point closest to $T_2$ on the receiver side of $T_2$. Whether a point is convex or non-convex is determined by the auxiliary function Convex($i$).

5.21.3 Determination of a Secondary Edge of the Primary Screen

If a secondary screen was found as described in Section 5.21.2 and $r_{scr2}(f)$ is equal to one at all frequencies, the “Screen” model is covered by Sub-model 6 (terrain with two screens). Otherwise, the next step will be to search for a secondary edge of the primary screen.

The selection of a secondary edge and the determination of the efficiency of the edge follow by and large the same principles used for the primary edge of the secondary screen. The main difference is that only points in the primary screen shape are considered with the
exclusion of \( W_1, W_2 \) and \( T_1 \). Therefore, if the primary screen shape consists of 3 points there is no secondary edge. If the primary screen shape consists of more than 3 points, the point with largest path length difference \( \Delta t_0 \) has to be selected in the same way as for the primary edge of the secondary screen (if the screen shape consists of four points the selection becomes simple as only one possible point exists). This point point is denoted \( T_{12} = (x_{T12}, z_{T12}) \).

The interpolation parameters \( r_{\text{Mll}}(\lambda), r_{\text{Fr}}(\lambda), r_{\text{Fz}}(\lambda) \), and \( r_{\text{w}}(\lambda) \) are calculated in the same way as for the secondary screen as described in Section 5.21.2 but \( T_2 \) is replaced by \( T_{12} \). The interpolation parameters are in this case denoted \( r_{\text{Mll}}(\lambda), r_{\text{Fr}}(\lambda), r_{\text{Fz}}(\lambda), \) and \( r_{\text{w}}(\lambda) \), respectively. The determination of the transition parameter \( r_{\text{scr}}(\lambda) \) of the secondary edge contains two more modifiers \( r'_{\text{fl}}(\lambda) \) and \( r'_{\text{Fz}}(\lambda) \). The purpose of the extra modifiers is to quantify that the shape \( T_1, T_{12}, W (=W_1 \text{ or } W_2) \) deviates significantly from the straight line \( T_1 \) to \( W \) from a propagation point of view.

\[ \text{Figure 34} \]
\[ \text{Definition of } h'_{\text{scr}} \text{ used for determination of } r'_{\text{fl}} \text{ and } r'_{\text{Fz}}. \]

In order to determine the height \( h'_{\text{scr}} \) defined in Figure 34, the point \( P_0 \) is determined by Eq. (311) if \( T_{12} \) is on the source side of \( T_1 \). If \( T_{12} \) is on the receiver side of \( T_1 \) \( S \) has to be replaced by \( R \) and \( W_1 \) by \( W_2 \).

\[
\frac{T_{12}P_0}{T_{12}P_1} = \frac{|T_{12}S|}{|T_{12}W_1|} \cdot \frac{T_{12}W_1}{T_{12}W_1'}
\]  

(311)

If \( P_0 = (x_0, z_0) \) \( h'_{\text{scr}} \) can be calculated by Eq. (312).
Finally $r'_{\lambda,12}(\lambda)$ and $r'_{Fz,12}(\lambda)$ are calculated according to Eq. (303) and (304). In the equations $h_{SCR} = h'_{SCR,12}$ and $h_{Fz}(\lambda)$ is determined by Eq. (313).

\[
h_{Fz}(\lambda) = \text{CalcFZd}(d_1, d_2, \pi/2, 0.5\lambda)
\]

where

\[
d_1 = \text{Length}(x_0, z_0, x'_{T12}, z'_{T12})
\]
\[
d_2 = \text{Length}(x_{T1}, z_{T1}, x'_{T12}, z'_{T12})
\]

The six interpolation parameters are finally combined into the transition parameter of the secondary edge $r_{scr,12}(f)$ calculated by Eq. (314).

\[
r_{scr,12}(f) = r_{A12}(f) r_{A12}(f) r_{Fz,12}(f) r_{SCR,12}(f) r_{Fz,12}(f)
\]

The purpose of transition parameter $r_{scr,12}$ is to combine the results by Sub-model 4 and 5 into a result by the “OneScreen” model and as shown in Eq. (315).

\[
\Delta L_{scr}(f) = r_{scr,12}(f) \Delta L_4(f) + (1 - r_{scr,12}(f)) \Delta L_4(f)
\]

### 5.21.4 Determination of Terrain Flatness

In the Section Determination of a Primary Edge of a Primary Screen the transition between the “NoScreen” and “Screen” model is described. The “NoScreen” model itself is a combination of the “Flat” model (Sub-model 1 or 2) and the “Non-flat terrain without screens” model (Sub-model 3). The transition between the “NoScreen” and “Screen” model is quantified by the transition parameter $r_{flat}$.

Before determining $r_{flat}$ the equivalent flat terrain has to be determined as described in Section 5.21.5. Then the source height $h_{Se}$, receiver height $h_{Re}$ and distance along the terrain $d_e$ measured relative to the equivalent flat terrain can be determined as shown in Eq. (316).

\[
(x'_{SGe}, z'_{SGe}, h'_{SGe}) = \text{NormLine}(x_{SGe}, z_{SGe}, x_{RGe}, z_{RGe}, x_S, z_S)
\]
\[
(x'_{RGe}, z'_{RGe}, h'_{RGe}) = \text{NormLine}(x_{SGe}, z_{SGe}, x_{RGe}, z_{RGe}, x_R, z_R)
\]
\[
d_e = \text{Length}(x'_{SGe}, z'_{SGe}, x'_{RGe}, z'_{RGe})
\]
\[
h_{Se} = \text{Max}(h'_{Se}, 0.01)
\]
\[
h_{Re} = \text{Max}(h'_{Re}, 0.01)
\]

The interpolation parameter $r_{f}(f)$ defining the “flatness” of the terrain can now be calculated by Eq. (317) where $\Delta R_2$ is the increase in path length if the flat terrain is displaced by downwards by $\Delta h$. $\Delta h$ is the average height of the terrain above the equivalent flat terrain calculated in Section 5.21.5. Eq. (317) is only used in the frequency range 25 Hz to 2000...
Hz. At higher frequencies the value at 2000 Hz is used to avoid that the terrain always will be interpreted as being non-flat at very high frequencies. \( r_f = 1 \) indicates a flat terrain while \( r_f = 0 \) indicates a non-flat terrain.

\[
\begin{align*}
    r_f(f) &= \begin{cases} 
        1 & \frac{\Delta R_2}{\lambda} \leq 0.01 \\
        0.02 - \frac{\Delta R_2}{\lambda} & 0.01 < \frac{\Delta R_2}{\lambda} < 0.03 \\
        0 & \frac{\Delta R_2}{\lambda} \geq 0.03
    \end{cases} \\
    \text{where} \\
    \Delta R_2 &= \sqrt{(h_{se} + h_{re} + 2\Delta h)^2 + d^2} - \sqrt{(h_{se} + h_{re})^2 + d^2}
\end{align*}
\]

(317)

Due to the fact that \( r_f \) according to Eq. (317) in most cases will be 1 at very low frequencies even in cases of a highly concavely shaped terrain where submodel 3 for non-flat is known to produce better result, the transition parameter is modified as shown in Eq. (393) based on the sum of Fresnel-zone weights for concave segments and the concave part of the transition segments in Sub-model 3.

\[
\begin{align*}
    r_{flat}(f) &= \begin{cases} 
        r_f & w_{con} \leq 1.05 \\
        1.4 - \frac{\sum_{i=1}^{N} w_{con}(f)}{0.35} & 1.05 < w_{con} < 1.4 \\
        0 & w_{con} \geq 1.4
    \end{cases} \\
    \text{where} \\
    w_{con}(f) &= \begin{cases} 
        w_i(f) & \text{for concave segments, from Eq.(131)} \\
        w_{i,concave}(f)r_i(f) & \text{for transition segments, from Eq.(152)} \\
        0 & \text{for convex segments}
    \end{cases}
\end{align*}
\]

(318)

The purpose of transition parameter \( r_{flat} \) is to combine the results by the “Flat” model (Sub-model 1 or 2) and Sub-model 3 for non-flat terrain without screens as shown in Eq. (319).

\[
\Delta L_{noscr}(f) = r_{flat}(f)\Delta L_{flat}(f) + (1 - r_{flat}(f))\Delta L_3(f)
\]

(319)

5.2.1.5 Equivalent Flat Terrain

The equivalent flat terrain is defined as the flat terrain giving the best fit to a non-flat terrain using the least squares method.
The equivalent flat terrain is defined by the coefficients $\alpha$ and $\beta$ as shown in Eq. (320).

$$z = \alpha + \beta x$$  \hspace{1cm} (320)

The first step when determining the parameters $\alpha$ and $\beta$ is to calculate the mean value of $x$ and $z$ as shown in Eq. (321).

$$\bar{x} = \frac{x_{n+2} + x_1}{2}$$

$$\bar{z} = \frac{1}{x_{n+2} - x_1} \sum_{i=1}^{n+1} \frac{1}{2} (x_i^2 - x_1^2) + (z_i - \gamma_i x_i)(x_{i+1} - x_i)$$  \hspace{1cm} (321)

where

$$\gamma_i = \frac{z_{i+1} - z_i}{x_{i+1} - x_i}$$

Then $\alpha$ and $\beta$ can be determined as shown in Eq. (322).

$$t_2 = \frac{\bar{x}^2 - x_1^2}{3} - \bar{x}(x_{n+2} - x_1^2) + \bar{x}^2(x_{n+2} - x_1)$$

$$t_1 = \sum_{i=1}^{n+1} \frac{1}{3} (x_i^2 - x_1^2) + \frac{z_i - \bar{z}}{2} \frac{x_i + \bar{x}}{x_{i+1} - x_1^2} + \bar{x}(\gamma_i x_i - z_i + \bar{z})(x_{i+1} - x_i)$$

$$\beta = \frac{t_1}{t_2}$$

$$\alpha = \bar{z} - \bar{x}\beta$$

The average height of the terrain $\Delta h$ above the equivalent flat terrain can subsequently be calculated based on the area of each segment $A_i$ above the equivalent flat terrain ($\Delta h$ will be the same if $A_i$ is the area of the terrain below the equivalent flat terrain) as shown in Eq. (323). $A_i$ is calculated as shown in the following.

$$\Delta h = \frac{1}{x_{n+2} - x_1} \sum_{i=1}^{n+1} A_i$$  \hspace{1cm} (323)

For each segment the vertical height of the terrain relative to the equivalent flat terrain $h_i$ at the start of the segment and $h_{i+1}$ at the end of the segment are determined by Eq. (324).

$$h_i = z_i - \alpha - \beta x_i$$

$$h_{i+1} = z_{i+1} - \alpha - \beta x_{i+1}$$  \hspace{1cm} (324)
If \( h_i \) and \( h_{i+1} \) have the same sign (\( h_i h_{i+1} \geq 0 \)) indicating that the segment and the equivalent flat terrain do not intersect, \( A_i \) is calculated by Eq. (325). If \( A_i < 0 \), \( A_i \) is set to 0 when applied in Eq. (323).

\[
A_i = \frac{h_{i+1} + h_i}{2} (x_{i+1} - x_i)
\]

If \( h_i \) and \( h_{i+1} \) have opposite signs (\( h_i h_{i+1} < 0 \)) indicating that the segment and the equivalent flat terrain intersects, \( A_i \) is calculated by Eq. (326). If \( A_i < 0 \), \( A_i \) is set to 0 when applied in Eq. (323).

\[
A_i = \begin{cases} 
\frac{h_i}{2} (x_s - x_i) & h_i > 0 \\
\frac{h_{i+1}}{2} (x_{i+1} - x_s) & h_i < 0 
\end{cases}
\]

where

\[
x_s = \frac{|h_i|}{|h_i| + |h_{i+1}|} (x_{i+1} - x_i) + x_i
\]

Instead of characterizing the equivalent flat terrain by the coefficients \( \alpha \) and \( \beta \), the terrain can also be characterized by start and end coordinates as defined as shown in Eq. (327).

\[
x_{SGe} = x_S \\
z_{SGe} = \alpha + \beta x_S \\
x_{BGe} = x_R \\
z_{SGe} = \alpha + \beta x_R
\]

5.21.6 Finite Screens

As already stated in Section 2 screens are in the Nordtest standard method assumed to have infinite horizontal length perpendicular to the direction of propagation. However, if a screen has a finite horizontal size a significant contribution of sound may propagate laterally from source to receiver around the vertical edges of the screen. This can be taken into account as described in the informative Annex E. It is in general recommended to ignore lateral diffraction in case of moving sources due to the averaging caused by the movement.

In some cases the height of the screen may vary laterally. For such screens the calculation is performed for a screen height determined by the average height within the significant part of the screen. The significant part of the screen is defined by the part of the screen which is inside the horizontal limits of the Fresnel-zone around the propagation path as shown in Figure 35.
The width of the Fresnel-zone defined by the distance \( d(\theta) \) from \( P_0 \) to \( P_l \) or \( P_r \) is determined by Eq. (328) where \( \theta \) is the angle between the line \( SR \) and \( P_0P_l \) or \( P_0P_r \). The constant 0.4 corresponds approximately to a frequency of 250 Hz and a fraction \( F_\lambda \) of the wavelength equal to \( \frac{1}{2} \).

\[
d(\theta) = \text{CalcFZd}(|SP_0|, |RP_0|, \theta, 0.4)
\]  

(328)

5.22 Compound Model

The sound pressure level \( L_R \) at the receiver is for each frequency band predicted according to Eq. (329).

\[
L_R(f) = L_w(f) + \Delta L_d + \Delta L_a(f) + \Delta L_s(f) + \Delta L_t(f) + \Delta L_{\lambda}(f)
\]  

(329)

\( \Delta L_d \) is the effect of free field attenuation in a homogeneous atmosphere due to spherical spreading of the sound energy and is calculated by Eq. (330).
$$\Delta L_d = -10 \log \left(4\pi R^2 \right)$$  \hspace{1cm} (330)\\

$\Delta L_a(f)$ is the effect of air absorption calculated by Sub-model 9 as shown in Eq. (331).

$$\Delta L_a(f) = \Delta L_a(f)$$  \hspace{1cm} (331)\\

$\Delta L_l(f)$ is the propagation effect of ground and screens. $\Delta L_l(f)$ is combined of several sub-models as shown in Eq. (332).

$$\Delta L_l(f) = \left(r_{scr1}(f)\Delta L_{scr}(f) + (1-r_{scr1}(f))\Delta L_{noscr}(f)\right) + \Delta L_l(f)$$  \hspace{1cm} (332)\\

$\Delta L_s(f)$ is the propagation effect of a scattering zone (mainly forest and other vegetation) calculated by Sub-model 10 as shown in Eq. (333). Another propagation effect of a scattering zone is that the coherence between rays are reduced in the ground and screen model used to predict $\Delta L_l(f)$. This is quantified by the coherence coefficient $F_s(f)$.

$$\Delta L_s(f) = \left\{ \begin{array}{ll} \Delta L_{10}(f) & \text{scattering zone along propagation path} \\ 0 & \text{otherwise} \end{array} \right.$$  \hspace{1cm} (333)\\

$\Delta L_r(f)$ is the propagation effect of a reflector calculated by Sub-model 11 as shown in Eq. (334).

$$\Delta L_r(f) = \left\{ \begin{array}{ll} \Delta L_{11}(f) & \text{propagation path is a reflection path} \\ 0 & \text{otherwise} \end{array} \right.$$  \hspace{1cm} (334)\\

5.23 **Auxiliary Functions**

This section contains a number of auxiliary functions used to solve a number of calculation problems in the method.

5.23.1 **Coft**

The function $Coft$ calculates the adiabatic sound speed $c$ (m/s) in dry air at the temperature $t$ (°C).

The sound speed $c$ is calculated by Eq. (335).
\( c = Coft(t) = 20.05 \sqrt{t} + 273.15 \) \hspace{1cm} (335)

5.23.2 Convex

The function \( Convex \) determines whether two terrain segments intersecting at \( P_i = (x_i, z_i) \) in the terrain profile form a convex shape (angle between segments above \( \pi \)) as shown in Eq. (336) where \( i \) is the terrain point number and \( b_{cvx} \) is a logical variable (1 means convex intersection, 0 if concave or straight).

\[
b_{cvx}(i) = Convex(i) = H\left(VertDist(x_{i-1}, z_{i-1}, x_{i+1}, z_{i+1}, x_i, z_i) - 0.0001\right)
\] \hspace{1cm} (336)

The value 0.0001 has been introduced to avoid numerical problems in the calculations.

5.23.3 \( Exp' \)

The function \( Exp' \) is a practically modified exponential function. The function is modified to be zero below the argument -2. The function is defined in Eq. (337).

\[
y = exp'(x) = \begin{cases} 
\exp(x) & x \geq -1 \\
(2 + x)\exp(1) & -2 < x < -1 \\
0 & x \leq -2 
\end{cases}
\] \hspace{1cm} (337)

5.23.4 CalcFZd

The function \( CalcFZd \) is used to calculate the distance from the reflection point \( O \) within the Fresnel-zone to a point on the elliptic Fresnel-zone in direction \( \theta \) as shown in Figure 36. \( S \) and \( R \) are the foci of the ellipse and \( r_S = |SO| \) and \( r_R = |RO| \).

\[ \begin{figure}
\centering
\includegraphics[width=0.5\textwidth]{figure36}
\caption{Definition of calculation parameters.}
\end{figure} \]

The function \( CalcFZd \) is defined by Eq. (338) where \( F_\lambda \) is the product of a fraction \( F \) and the wavelength \( \lambda \).
The distance \( d = \text{CalcFZd}(r_s, r_R, \theta, F_\lambda \lambda) \) (338)

The distance \( d = |\text{OP}| \) is calculated as shown in Eq. (339).

\[
\begin{align*}
    r &= r_s + r_R \\
    \ell &= r + F_\lambda \lambda \\
    A &= 4 \left( \ell^2 - (r \cos \theta)^2 \right) \\
    B &= 4 r \cos \theta \left( r_R^2 - r_s^2 \right) + 4 \left( r_s - r_R \right) \ell^2 \cos \theta \\
    C &= -\ell^4 + 2 \left( r_s^2 + r_R^2 \right) \ell^2 - (r_s^2 - r_R^2) \\
    d &= \frac{-B \pm \sqrt{B^2 - 4AC}}{2A}
\end{align*}
\]

### 5.23.5 FresnelZoneSize

The function \( \text{FresnelZoneSize} \) calculates the size of a Fresnel-zone of a reflecting plane assuming a non-refracting atmosphere. The function is defined by Eq. (340).

\[
(a_1, a_2, b) = \text{FresnelZoneSize}(d, h_s, h_R, F_\lambda \lambda)
\]

(340)

where

- \( d \) is the distance from image source \( S' \) to receiver \( R \) measured along the reflection plane
- \( h_s \) is the height of the source above the plane
- \( h_R \) is the height of the receiver above the plane
- \( F_\lambda \lambda \) is the product of a fraction \( F_\lambda \) and the wavelength \( \lambda \)
- \( a_1 \) is the distance from the reflection point \( O \) to the source side Fresnel-zone borderline in the direction of propagation
- \( a_2 \) is the distance from the reflection point \( O \) to the receiver side Fresnel-zone borderline in the direction of propagation
- \( b \) is half the width of the Fresnel-zone perpendicular to the direction of propagation

The variables are defined in Figure 37.
**Figure 37**
Definition of variables used when calculating the size of the Fresnel-zone in case of reflection by a plane surface.

The variables $a_1$, $a_2$, and $b$ are calculated by Eqs. (341) to (343).

\[
a_1 = |P_1O| = \text{CalcFZd} \left( r_s, r_R, \pi - \psi_G, F_\lambda \right)
\tag{341}
\]

\[
a_2 = |P_2O| = \text{CalcFZd} \left( r_s, r_R, \psi_G, F_\lambda \right)
\tag{342}
\]

\[
b = \sqrt{\frac{\text{CalcFZd} \left( r_s, r_R, \frac{\pi}{2}, F_\lambda \right)^2}{1 - \left( \frac{a_2 - a_1}{a_2 + a_1} \right)^2}}
\tag{343}
\]

In Eqs. (341) to (343) $r_s$, $r_R$ and $\psi_G$ are determined as shown in Eq. (344).

\[
\psi_G = \arctan \left( \frac{h_s + h_R}{d} \right)
\]

\[
r = \sqrt{(h_s + h_R)^2 + d^2}
\]

\[
r_s = \frac{h_s}{h_s + h_R} r
\]

\[
r_R = \frac{h_R}{h_s + h_R} r
\]

\tag{344}
5.23.6 FresnelZoneW

The function FresnelZoneW calculates the frequency dependent Fresnel-zone weight of a ground segment assuming a refracting atmosphere. The function is defined by Eq. (345).

\[
\left( w(f), \tilde{d}, \tilde{h}_s, \tilde{h}_r, \tilde{d}_{refl} \right) = \text{FresnelZoneW}(d, h_s, h_r, d_1, d_2, F_{\lambda}, \zeta, c_0)
\]  

(345)

where

- \(d\) is the horizontal distance measured along the extended ground segment from source S to receiver R
- \(h_s\) is the height of S above the extended ground segment (if \(h_s < 0.01\), \(h_s = 0.01\) is used instead)
- \(h_r\) is the height of R above the extended ground segment (if \(h_r < 0.01\), \(h_r = 0.01\) is used instead)
- \(d_1\) is the horizontal distance measured along the extended ground segment from source S to end point of the ground segment closest to S
- \(d_2\) is the horizontal distance measured along the extended ground segment from source S to end point of the ground segment closest to R
- \(F_{\lambda}\) is the product of a fraction \(F_\lambda\) and the wavelength \(\lambda\)
- \(\zeta\) is the relative sound speed gradient in the equivalent linear sound speed profile
- \(c_0\) is the sound speed at the ground in the equivalent linear sound speed profile
- \(\tilde{d}, \tilde{h}_s, \tilde{h}_r, \tilde{d}_{refl}\) are the modified propagation variables corresponding to the modified source S’ and receiver position R’ when the curved ray case is transformed into the straight ray case as described in the following.

The first step is to determine the position of the reflection point defined by the horizontal distance \(d_{refl}\) measured along the extended ground segment from source S, the grazing reflection angle \(\psi_G\), and the ray path distances from source to reflection point \(R_S\) and from receiver to reflection point \(R_R\) taking into account the effect of refraction. This is done according to Eq. (346) if the receiver is not in the shadow zone (is determined by Eq. (43) in Section 5.5.4).

\[
(NA, NA, R_S, R_R, NA, NA, \psi_G, d_{refl}) = \text{ReflectedRay}(d, h_s, h_r, \zeta, c_0)
\]  

(346)

The variables are shown in Figure 38.
Figure 38
Definition of variables when determining of the Fresnel-zone weight in case of refraction (circular rays).

If the receiver is in the shadow zone the variables are instead determined by Eq. (347).

$$\psi_G = 0$$

$$d_{\text{refl}} = d \frac{\sqrt{h_s}}{\sqrt{h_s} + \sqrt{h_R}}$$

$$R_s = R_0 \arccos \left( 1 - \frac{h_s}{R_0} \right)$$

$$R_r = R_0 \arccos \left( 1 - \frac{h_r}{R_0} \right)$$

where

$$R_0 = \left( \frac{d}{2\left(\sqrt{h_s} + \sqrt{h_R}\right)} \right)$$

In order to calculate the size of the Fresnel-zone by the auxiliary function $FresnelZoneSize$ valid for a non-refracting atmosphere the curved ray case is transformed into the straight ray case by determining modified source and receiver positions $S'$ and $R'$ as indicated in Figure 38. The modified variables $d'$, $h'_s$, $h'_r$ and $d'_{\text{refl}}$ are calculated by Eq. (348). $d'_{\text{refl}}$ is
horizontal distance from the modified source S’ to the reflection point measured along the extended ground segment.

\[ \tilde{d} = (R_S + R_R) \cos \psi_G \]
\[ \tilde{h}_S = R_S \sin \psi_G \]
\[ \tilde{h}_R = R_R \sin \psi_G \]
\[ \tilde{d}_{\text{refl}} = R_S \cos \psi_G \]  

(348)

Now the position of the Fresnel-zone borders in the direction of propagation relative to the reflection point can be determined by Eq. (349) and (350). \(d_{1,Fz}\) and \(d_{2,Fz}\) are the horizontal frequency dependent distance measured along the extended ground segment from source S to end point of the ground segment closest to S and R, respectively.

\[ (a_1(f), a_2(f), NA) = FresnelZoneSize(d_{1,Fz}, h_S, h_R, F_z, \lambda) \]  

(349)

\[ d_{1,Fz}(f) = d_{\text{refl}} - a_1(f) \]
\[ d_{2,Fz}(f) = d_{\text{refl}} + a_2(f) \]  

(350)

The frequency dependent Fresnel-zone weight \(w(f)\) can now be determined by Eq. (351).

\[ w(f) = \begin{cases} 0 & d_1 \geq d_{2,Fz} \lor d_2 \leq d_{1,Fz} \\ 1 & d_1 \leq d_{1,Fz} \land d_2 \geq d_{2,Fz} \\ (d_2 - d_{1,Fz})/(d_{2,Fz} - d_{1,Fz}) & d_1 > d_{1,Fz} \land d_2 < d_{2,Fz} \\ (d_2 - d_{1,Fz})/(d_{2,Fz} - d_{1,Fz}) & d_1 \leq d_{1,Fz} \land d_2 < d_{2,Fz} \\ (d_{2,Fz} - d_1)/(d_{2,Fz} - d_{1,Fz}) & d_1 > d_{1,Fz} \land d_2 \geq d_{2,Fz} \end{cases} \]  

(351)

5.23.7 FresnelZoneWm

The function \(FresnelZoneWm\) calculates a modified Fresnel-zone weight \(w'(f)\) of a ground segment assuming a refracting atmosphere. The function is defined by Eq. (352).

\[ w'(f) = FresnelZoneWm(d_{1,Fz}, h_S, h_R, d_1, d_2, F_z, \lambda, \xi, c_0) \]  

(352)

The input variables are the same as for the function \(FresnelZoneW\) described in Section 5.23.6. The procedure for calculating the weight is the same as described in Section 5.23.6 except that the Eq. (351) has been replaced by Eq. (353). According to the principle in Eq. (353) the contribution to the Fresnel-zone weight on each side of the reflection point is the same size.
\[ w(f) = 0.5(w_s(f) + w_r(f)) \]

where

\[
w_s(f) = \begin{cases} 
0 & d_1 \geq d_{refl} \lor d_2 \leq d_{1,Fz} \\
1 & d_1 \leq d_{1,Fz} \land d_2 \geq d_{refl} 
\end{cases} \]

\[
w_r(f) = \begin{cases} 
(d_2 - d_1)/(d_{refl} - d_{1,Fz}) & d_1 > d_{1,Fz} \land d_2 < d_{refl} \\
(d_2 - d_{1,Fz})/(d_{refl} - d_{1,Fz}) & d_1 \leq d_{1,Fz} \land d_2 < d_{refl} \\
(d_{2,Fz} - d_1)/(d_{refl} - d_{1,Fz}) & d_1 > d_{1,Fz} \land d_2 \geq d_{refl} 
\end{cases}
\] (353)

5.23.8 \(H\)

The function \(H(x)\) is Heavisides step function calculated as shown in Eq. (354).

\[ H(x) = \begin{cases} 
1 & x \geq 0 \\
0 & x < 0 
\end{cases} \] (354)

5.23.9 HeightOfCircularRay

The function \(HeightOfCircularRay\) calculates the height of a circular ray. As shown in Figure 39 the ray starts at the point \((0,h_1)\) and ends at the point \((d,h_2)\). The curvature of the ray corresponds to a relative sound speed gradient \(\xi\). The function calculates the height of the ray \(h_0\) at point \(P_0\) in the horizontal distance \(d_0\) from the start of the ray as defined in Eq. (355). The function also calculates the lengths of the ray \(R_1\) and \(R_2\) from \(P_0\) to the starting and end points, respectively.
Figure 39
Definition of geometrical parameters in the function HeightOfCircularRay.

\[ (h_0, R_1, R_2) = \text{HeightOfCircularRay}(d, h_1, h_2, \xi, d_0) \]  \hspace{1cm} (355)

In order to normalise the problem to the solution given in Section 5.5.4, the parameters \( \xi', d_0', h_1' \) and \( \Delta h \) are defined as shown in Eqs. (356) to (361).

\[ \xi' = |\xi| \] \hspace{1cm} (356)

\[ \Delta h = |h_1 - h_2| \] \hspace{1cm} (357)

\[ \xi > 0 \land h_1 > h_2 : \quad h_1' = h_2, \quad d_0' = d - d_0 \] \hspace{1cm} (358)

\[ \xi > 0 \land h_1 \leq h_2 : \quad h_1' = h_1, \quad d_0' = d_0 \] \hspace{1cm} (359)

\[ \xi < 0 \land h_1 \geq h_2 : \quad h_1' = -h_1, \quad d_0' = d_0 \] \hspace{1cm} (360)

\[ \xi < 0 \land h_1 < h_2 : \quad h_1' = -h_2, \quad d_0' = d - d_0 \] \hspace{1cm} (361)

Now the height \( h_0 \) can be determined by Eqs. (362) to (367) where \( \text{Sign}(x) \) is the signum function. \((x_0, z_0)\) is the centre of circular ray with radius of curvature \( R_c \).

\[ \tan \psi_L = \frac{\xi'}{d} + \frac{\Delta h (2 + \xi' \Delta h)}{2d} \] \hspace{1cm} (362)

\[ x_0 = \frac{\tan \psi_L}{\xi'} \] \hspace{1cm} (363)
\[ z_0 = h'_1 - \frac{1}{\xi'} \]  
(364)

\[ R_c = \frac{1}{\xi'} \cos(\psi_L) \]  
(365)

\[ \theta = \arccos\left(\frac{d_0' - x_0}{R_c}\right) \]  
(366)

\[ h_0 = \text{Sign}(\xi)\left(R_c \sin(\theta) + z_0\right) \]  
(367)

Finally, \( R_1 \) and \( R_2 \) can be calculated by Eq. (368).

\[ R_1 = 2R_c \arcsin\left(\frac{r_1}{2R_c}\right) \]  
\[ R_2 = 2R_c \arcsin\left(\frac{r_2}{2R_c}\right) \]  
(368)

where

\[ r_1 = \text{Length}(0, h_1, d_0, h_0) \]
\[ r_2 = \text{Length}(d_0, h_0, d, h_2) \]

5.23.10 ImagePoint

The function \textit{ImagePoint} calculates the coordinates of the image \( P_{\text{image}} \) of a point \( P \) reflected in a line \( P_1P_2 \) as shown in Eq. (369).

\[ (x_i, y_i) = \text{Length}(x_1, y_1, x_2, y_2, x, y) \]  
(369)

where

\[ P = (x, y) \]
\[ P_1 = (x_1, y_1) \]
\[ P_2 = (x_2, y_2) \]

\[ P_{\text{image}} = (x_i, y_i) \]

The coordinates of \( P_{\text{image}} \) is calculated by Eq. (370).
\[(x_0, y_0, NA) = \text{NormLine}(x_1, y_1, x_2, y_2, x, y)\]

\[x_i = 2x_0 - x\]
\[z_i = 2z_0 - z\]

5.23.11 Length

The function \textit{Length} calculates the length of a line \(P_1P_2\) as shown in Eq. (371).

\[d = \text{Length}(x_1, y_1, x_2, y_2)\]  (371)

where

\[P_1 = (x_1, y_1)\]
\[P_2 = (x_2, y_2)\]

\(d\) is the distance between \(P_1\) and \(P_2\)

The distance \(d\) is calculated by Eq. (372)

\[d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}\]  (372)

5.23.12 \textit{MinConcaveHeight}

The function \textit{MinConcaveHeight} calculates the smallest source or receiver height where the end point of the ground segment closest to the source or receiver point under consideration is at the border of the Fresnel-zone. This height which depends on the frequency is used in Sub-model 3 (non-flat terrain without screening effects) to determine whether a segment is concave or not. The principle is illustrated in Figure 40 for the source case.
Figure 40
Definition of the principle for calculating the minimum source height $h_{S,Fz}$ of a concave segment and definition of variables used in the calculation.

The function is defined by Eq. (373) where the variables $h_R$, $d_1$ and $d = d_1 + d_2$ are defined in Figure 40 and where $\lambda$ is the wavelength. The same function is used to calculate $h_{R,Fz}$ by interchanging S and R.

$$h_{S,Fz}(f) = \text{MinConcaveHeight}(h_R, d_1, d, \lambda)$$  \hspace{1cm} (373)

If Eq. (374) is fulfilled $h_{S,Fz}(f)$ is set equal to $\infty$. Otherwise $h_{S,Fz}$ is calculated by Eq. (375) where $F_\lambda = 1/16$. The variables A, B, C, $x_1$ and $x_2$ in Eq. (375) are a function of the frequency although not indicated.

$$\sqrt{d_2^2 + h_R^2} - h_R \leq F_\lambda \lambda$$  \hspace{1cm} (374)

$$h_{S,Fz}(f) = -B - \sqrt{B^2 - 4 AC}$$

$$2A$$

where

$A = 4 h_R^2 - 4 x_1$

$B = 4 h_R x_2$

$C = x_2^2 - 4 d_1^2 x_1$

and

$$x_1 = \left( \sqrt{(h_R^2 + d_2^2) - F_\lambda \lambda} \right)^2$$

$$x_2 = h_R^2 + (d_1 + d_2)^2 - d_1^2 - x_1$$
5.23.13 NormLine

The function *NormLine* determines the projection of a point $P$ onto a line $P_1P_2$ and the signed distance to the directed line as shown in Eq. (376).

$$(x_0, y_0, d) = \text{NormLine}(x_1, y_1, x_2, y_2, x, y) \quad (376)$$

where

$P = (x, y)$

$P_1 = (x_1, y_1)$

$P_2 = (x_2, y_2)$

$P_0 = (x_0, y_0)$ is the projection point

$d$ is the signed distance to the line. Positive and negative values indicate that the point $P$ is left or right of the line, respectively.

The projection point $P_0$ and the distance $d$ is calculated by Eq. (377).

$$x_{21} = x_2 - x_1$$

$$y_{21} = y_2 - y_1$$

$$x_{01} = x - x_1$$

$$y_{01} = y - y_1$$

$$c = \frac{(x_{21}x_{01} + y_{21}y_{01})}{(x_{21}^2 + y_{21}^2)}$$

$$x_0 = cx_{21} + x_1$$

$$y_0 = cy_{21} + y_1$$

$$d = \frac{(x_{21}y_{01} - y_{21}x_{01})}{\sqrt{x_{21}^2 + y_{21}^2}}$$

5.23.14 PhaseDiffFreq

The function *PhaseDiffFreq* calculates a frequency $f_{\Delta \alpha}$ corresponding to a phase difference $\Delta \alpha$ between direct sound and sound reflected by flat ground in case of straight line propagation (homogeneous atmosphere) as shown in Eq. (378) where $d$ is the horizontal propagation distance, $h_S$ is the source height, $h_R$ is the receiver height, $Z_G(f)$ is the terrain impedance as a function of the one-third octave band frequency from 25 Hz to 10 kHz, and the $c_0$ is the sound speed at the ground.

$$f_{\Delta \alpha} = \text{PhaseDiffFreq}(d, h_s, h_r, Z_G(f), c_0, \Delta \alpha) \quad (378)$$
The phase shift $\Delta \alpha(f)$ is calculated at the frequency $f$ by Eq. (379) where $\arg$ is the argument of the plane-wave reflection coefficient $R_p$ (complex number). $\Delta \alpha$ given by Eq. (379) is increasing with the frequency.

$$\Delta \alpha(f) = \frac{2\pi f}{c_0} \Delta R + \arg \left( \hat{R}_p(f, \psi_G) \right)$$

where

$$\Delta R = \sqrt{d^2 + (h_S + h_R)^2} - \sqrt{d^2 + (h_S - h_R)^2}$$

$$\psi_G = \arcsin \left( \frac{h_S + h_R}{\sqrt{d^2 + (h_S + h_R)^2}} \right)$$

The problem of determining the frequency $f$ corresponding to the phase shift $\Delta \alpha$ using Eq. (379) can only be solved by iteration. In order to reduce the calculation time the recommended procedure is to calculate $\Delta \alpha$ at the one-third octave band frequencies until $\Delta \alpha$ is within the range of two neighbouring frequencies (denoted $f_1$ and $f_2$). Interpolation with the logarithmic frequency is used to obtain the value $f_{\Delta \alpha}$ corresponding $\Delta \alpha$ as shown in Eq. (380).

$$\log(f_{\Delta \alpha}) = \frac{\Delta \alpha - \Delta \alpha(f_1)}{\Delta \alpha(f_2) - \Delta \alpha(f_1)} (\log(f_2) - \log(f_1)) + \log(f_1)$$

If $\Delta \alpha$ is greater than $\Delta \alpha(10 \text{ kHz})$, linear extrapolation based on the values at 8 and 10 kHz is used up to 100 kHz. Above 100 kHz the value at 100 kHz is used. If $\Delta \alpha$ is less than $\Delta \alpha(25 \text{ Hz})$, logarithmic extrapolation is used as shown by Eq. (381).

$$f_{\Delta \alpha} = 25 \frac{\Delta \alpha}{\Delta \alpha(25 \text{ Hz})}$$

### 5.23.15 SegmentVariables

The function `SegmentVariables` determines the geometrical variables needed for a terrain segment as defined in Eq. (382) where $(x_S, z_S)$ are the source coordinates, $(x_R, z_R)$ are the receiver coordinates, and $(x_1, z_1)$ and $(x_2, z_2)$ are the segment end coordinates ($x_2 > x_1$).

$$\left( d', h'_S, h'_R, d'_1, d'_2 \right) = \text{SegmentVariables} \left( x_S, z_S, x_R, z_R, x_1, z_1, x_2, z_2 \right)$$

The calculated variables are:

- $d'$ is the horizontal distance measured along the extended ground segment from source $S$ to receiver $R$
- $h'_S$ is the perpendicular distance from $S$ to the extended ground segment
$h'_R$ is the perpendicular distance from $R$ to the extended ground segment.

$d'_i$ is the signed distance measured along the extended ground segment from source $S$ to end point $(x_i, z_i)$. $d'_i = 0$ means $(x_i, z_i)$ is below the source while $d'_i = d'$ means below the receiver.

$d'_2$ is the signed distance measured along the extended ground segment from source $S$ to end point $(x_2, z_2)$.

The variables are calculated as shown in Eq. (383).

$$(x'_S, z'_S, h'_S) = \text{NormLine}(x_1, z_1, x_2, z_2, x_S, z_S)$$

$$(x'_R, z'_R, h'_R) = \text{NormLine}(x_1, z_1, x_2, z_2, x_R, z_R)$$

$$d' = \text{Length}(x'_S, z'_S, x'_R, z'_R)$$

$$|d'_1| = \text{Length}(x'_S, z'_S, x_1, z_1)$$

$$|d'_1| = \text{Length}(x'_R, z'_R, x_1, z_1)$$

$$|d'_2| = \text{Length}(x'_S, z'_S, x_2, z_2)$$

$$|d'_2| = \text{Length}(x'_R, z'_R, x_2, z_2)$$

$$d'_1 = \begin{cases} -|d'_1| & \text{if } |d'_1| < |d'_1| \land |d'_2| > d' \\ |d'_1| & \text{otherwise} \end{cases}$$

$$d'_2 = \begin{cases} -|d'_2| & \text{if } |d'_2| < |d'_1| \land |d'_2| > d' \\ |d'_2| & \text{otherwise} \end{cases}$$

5.23.16 ShadowZoneShielding

The function $\text{ShadowZoneShielding}$ determines the part of the attenuation in a meteorological shadow zone that is called the shadow zone shielding in the Nord2000 method as defined in Eq. (384).

$$\Delta L_{SZ}(f) = \text{ShadowZoneShielding}(f, d, h_S, h_R, \xi, c_0 d_{SZ})$$

where

$f$ is the frequency

$d$ is the horizontal source-receiver distance

$h_S$ is the source height

$h_R$ is the receiver height
ξ is the relative sound speed gradient in the equivalent linear sound speed profile

\(c_0\) is the sound speed at the ground in the equivalent linear sound speed profile

d\(_{SZ}\) is shadow zone distance defined in Section 5.5.4.

The shadow zone shielding contribution is based on the attenuation of an equivalent wedge. The geometry of the wedge is defined in Figure 41. The height of the wedge \(h_{SZ}\) is determined as illustrated in Figure 42 and depends on the curvature of a source-receiver ray.

**Figure 41**
Equivalent wedge used to calculate the shadow zone shielding contribution.

**Figure 42**
Ray defining the equivalent wedge used to calculated the shadow zone shielding contribution.

To determine \(h_{SZ}\) a frequency dependent relative sound speed profile \(\xi_{SZ}\) is determined by Eq. (385).

\[
\xi_{SZ}(f) = \begin{cases} 
\xi & f < 2000 \\
\frac{\log(f) - \log(20)}{\log(2000) - \log(20)} & f \geq 2000
\end{cases}
\]  

(385)

The next step is to determine the height of the ray \(h_{SZ}\) at the horizontal distance \(d_{SZ}\) using the auxiliary function \(HeightOfCircularRay\). \(h_{SZ}\) depends on the frequency as shown in Eq. (386).
\[ h_{SZ}(f) = \text{HeightOfCircularRay}(d, h_1, h_2, \xi_{SZ}(f), d_{SZ}) \] (386)

Finally the attenuation is calculated by Eq. (387).

\[ \Delta L_{SZ}(f) = 10 \log(2 R_{sk} \left| p_{wedge}(f, \beta, \theta_s, \theta_r, \tau, \tau_s, \tau_r, \ell, R_s, R_r) \right|) \]

where

\[ \theta_s = \pi + \arctan\left(\frac{h_{SZ}(f)}{d_{SZ}}\right) + \arctan\left(\frac{h_{SZ}(f)}{d - d_{SZ}}\right) \]

\[ \theta_r = 0 \]

\[ \beta = \theta_s \]

\[ R_s = \sqrt{R_{SZ}(f)^2 + d_{SZ}^2} \]

\[ R_r = \sqrt{R_{SZ}(f)^2 + (d - d_{SZ})^2} \]

\[ \ell = R_s + R_r \]

\[ \tau_s = \frac{R_s}{c_0} \]

\[ \tau_r = \frac{R_r}{c_0} \]

\[ \tau = \frac{\ell}{c_0} \] (387)

5.23.17 Sign

The function \( \text{Sign}(x) \) is the signum calculated as shown in Eq. (388).

\[ \text{Sign}(x) = \begin{cases} 
1 & x > 0 \\
0 & x = 0 \\
-1 & x < 0 
\end{cases} \] (388)

5.23.18 VertDist

The function \( \text{VertDist} \) determines the vertical signed height \( \Delta z \) from a point \( P \) to a directed line \( P_1P_2 \) as shown in Eq. (389).

\[ \Delta z = \text{VertDist}(x_1, z_1, x_2, z_2, x, z) \] (389)

where

\[ P = (x,z) \]
\[ P_1 = (x_1, y_1) \]
\[ P_2 = (x_2, y_2) \]

\( \Delta z \) is the signed vertical height above the line. Positive and negative values indicate that the point \( P \) is above or below the directed line \((x_2 > x_1)\), respectively.

The height \( \Delta z \) is calculated by Eq. (390).

\[
\Delta z = z - z_1 - (z_2 - z_1) \frac{x - x_1}{x_2 - x_1}
\]

\((390)\)

5.23.19 WedgeCross

The function \textit{WedgeCross} determines the top point of the equivalent wedge defined by two non-adjacent ground segments as shown in Eq. (391). It is required that \( x_1 < x_2 < x_3 < x_4 \). The geometrical variables are defined in Figure 43 and the coordinates \((x_0, z_0)\) are calculated as shown in Eq. (392).

\[
(x_0, z_0) = \text{WedgeCross}(x_1, z_1, x_2, z_2, x_3, z_3, x_4, z_4)
\]

\((391)\)

where

\((x_1, z_1)\) is the start point of the source side segment

\((x_2, z_2)\) is the end point of the source side segment

\((x_3, z_3)\) is the start point of the receiver side segment

\((x_3, z_3)\) is the end point of the receiver side segment

\((x_0, z_0)\) is the top point of the equivalent wedge

\[ \text{Figure 43} \]

\textit{Definition of equivalent wedge determined by two non-adjacent ground segments.}
\[ D = (x_2 - x_1)(z_4 - z_1) - (x_4 - x_3)(x_4, z_4) \]
\[ s = \frac{(x_4 - x_1)(z_4 - z_3) - (x_4 - x_3)(z_4 - z_1)}{D} \]
\[ t = \frac{(x_2 - x_1)(z_4 - z_1) - (x_4 - x_1)(z_2 - z_1)}{D} \]
\[ s \geq 1 \land t \geq 1: \begin{cases} x_0 = x_1 + (x_2 - x_1)s \\ z_0 = z_1 + (z_2 - z_1)s \end{cases} \]
\[ t < 1: \begin{cases} x_0 = x_3 \\ z_0 = z_3 \end{cases} \]
\[ s < 1: \begin{cases} x_0 = x_2 \\ z_0 = z_2 \end{cases} \]

5.23.20 Other Auxiliary Functions

Some auxiliary functions have been defined throughout the sections of Nordtest method and is therefore not mentioned in Section 5.23. These functions are mentioned in Table 10 below with a reference to the section where they have been described.

5.24 References

Annex A (Informative)
Composite Noise Sources

Most often “real” noise sources cannot be approximated by a single point source. In this case the real source which is denoted the extended source in the Nord2000 methodology has to be approximated by a number of incoherent point sources. Subsequently a calculation is performed for each sub-source and the sound pressure levels of the sub-sources are added incoherently.

Another case where the use of a single point source is insufficient is moving sources (e.g. road or railway traffic). A moving source sometimes called an incoherent line source can be approximated by a number of source points along the source track. A suitable incremental distance, angle or time spacing between points must be chosen to ensure that the point is representative to the propagation condition of any point on the small track segment where the source point is placed in the middle. A discussion of the topic can be found in [1].
Annex B (Informative)

Determination of the Simplified Terrain from the Actual Terrain

A method has been outlined in ref. [1] for approximating any real terrain shapes possibly defined on basis of digital elevation data by a segmented terrain. When using the method, artificial screens should be preferably be ignored.

The method is based on “the maximum deviation principle” in which the ground point P having the maximum perpendicular distance $r_{\text{max}}$ to the line between the first and the last ground point $P_1$ and $P_2$ will become a new ground point in the segmented terrain. The principle is illustrated in Figure 47.

![Figure 47](image)

**Figure 47**

“Maximum deviation principle” used to determine a new ground point

In the first step the ground point P between $P_1$ (equal to the source ground point $S_G$) and $P_2$ (equal to the receiver ground point $R_G$) is determined according to the maximum deviation principle. If $r_{\text{max}}$ is below a specified limit the terrain is defined as being flat but if not, P will become a new ground point in the simplified terrain shape which now consists of two straight segments $P_1P$ and $PP_2$.

In the next step the process is repeated for the two ground shapes $P_1$ to P and P to $P_2$. $r_{\text{max}}$ is determined for each of these two shapes and the point corresponding to the largest value of $r_{\text{max}}$ will become the next ground point in the simplified shape which now consists of three segments.

This process may be repeated to any degree of perfection but each time a new point is added, an existing segment is replaced by two new segments. As the calculation time of the Nord2000 propagation model will increase strongly with the number of segments this should only be repeated until deviations between the real and the segmented terrain are within acceptable limits.
It is recommended that additional extra ground points are added to the segmented terrain until the following requirements are fulfilled:

- The maximum deviation \( r_{\text{max}} \) fulfils a distance dependent requirement as e. g. shown in Eq. (393)

- The length of the segments \( d_{\text{segm}} \) fulfils a distance dependent requirement as e. g. shown in Eq. (393)

- The maximum number of segments is \( N_{\text{ts, max}} \). For most purposes \( N_{\text{ts, max}} = 10 \) seems to be a reasonable choice.

\[
\begin{align*}
r_{\text{max}} & \leq \begin{cases} 
0.1 & d \leq 50 \\
0.002 \, d & 50 < d < 500 \\
1 & d \geq 500 
\end{cases} \\
d_{\text{segm}} & \leq \begin{cases} 
1 & d \leq 20 \\
0.05 \, d & 20 < d < 200 \\
10 & d \geq 200
\end{cases}
\end{align*}
\] (393)

The outlined procedure shall only be considered a proposal and the requirement in Eq. (393) depends on the purpose of the calculations. If a more efficient procedure can be developed, such a method should be used instead.

The “maximum deviation principle” described above is applicable if no part of the terrain is causing significant shielding effects. If one or more parts of the terrain produce screening effects the screen or screens has to be identified and the “screen shape” has to be determined and simplified as described in Section 5.21. The rest of the terrain between source and screen, between screen and receiver and between the two screens in the double screen case is simplified using the “maximum deviation principle”. When simplifying the terrain between source and the screen closest to source the receiver is replaced by the top of the screen. When simplifying the terrain between the receiver and the screen closest to receiver the source is replaced by the top of the screen. When simplifying the terrain between two screens source and receiver are replaced by the screen tops. Where the maximum number of segments \( N_{\text{ts, max}} \) for terrain with no significant shielding effects is recommended to be in the order of 10, an order of 5 is recommended for terrain before, after or between screens.
Annex C (Informative)
Other Impedance Models

Only the Delany and Bazley impedance model described in Section 5.6.2 is used in the Nord2000 method and the frequency dependent sound speed profile linearization principle described in Section 5.5.3 is closely related to this impedance model. The use of the Nord2000 method has shown that other impedance models can be applied with a reasonable accuracy. However, a preliminary investigation shows that a frequency independent linearization similar to hard surfaces should be preferred in the whole frequency range until this topic has been investigated more closely.
Annex D (Informative)

Change in Vertical Source Emission Angle due to Refraction

If the noise source has a vertical directivity it has been assumed so far when applying the Nord2000 method that the vertical source emission angle is defined by the direction from the source to the receiver. In case of refraction this is a reasonable assumption when the vertical directivity is not too strong or when the refraction is moderate. However, in cases of strong vertical directivity and strong refraction this may not necessarily be true. In such cases it can be necessary to correct the vertical source emission angle for the effect of refraction. A simplified method for estimating the effect of atmospheric refraction on the source emission angle can be found in the DELTA report AV 1025/06: “Change in Source Emission Angle due to Refraction, Simplified Method”. The method determines the vertical change in source emission angle in relation to the source emission angle of a non-refracting atmosphere.
Annex E (Informative)

Lateral Diffraction of Finite Screens

In Sub-models 4-6 described in Section 5.13 through 5.15 which include screen effects it is assumed that the screens have an infinite length. In practice, screens will have a finite length and it is therefore possible that the screen effect will be reduced significantly when sound is diffracted laterally around the vertical edges of the screen. In Nord2000 this phenomena is called lateral diffraction. Figure 45 shows the basic case where a finite screen blocks the direct propagation but where sound is diffracted around the vertical edges reducing the efficiency of the screen compared to an infinite screen. Figure 46 shows another important case where the direct line from source to receiver is unblocked but where a part of the sound field is affected by the finite screen which will increase the attenuation at the receiver compared to a situation where the screen is ignored. Both cases are included in the Nord2000 method.

Figure 45
Finite screen with vertical edges at P₁ to P₂ blocking the propagation plane from the source S to the receiver R (top view).
Figure 46
Finite screen with vertical edges at $P_1$ to $P_2$ outside the propagation plane from the source $S$ to the receiver $R$ (top view).

The contribution from lateral diffraction is taken into account by adding additional propagation paths as shown in Figure 47. Such a propagation path is in the method called a lateral diffraction path. Normally two lateral diffraction paths are added for each end of the finite screen as shown in the figure (Plane 1 and 2). The path is going from $S$ to $R$ via $P_1$ or $P_2$.

Figure 47
Lateral dispersion paths for the case where the direct source receiver path is blocked by the finite screen.
The sound pressure is calculated for each lateral diffraction path using the comprehensive propagation model with propagation parameters measured along the vertical propagation planes and added after a correction for the screening effect of the vertical edges.

The sound pressure level from a lateral diffraction path is predicted by the same propagation model used for the direct path on basis of the propagation parameters determined along the lateral diffraction path but ignoring the finite screen. However, the propagation effects in Eq. (1) will in this case also include the propagation effect $\Delta L_v$ which is a correction for diffraction around the vertical edge. The sound pressures corresponding to lateral diffraction path 1 and 2 (plane 1 and 2) and the direct propagation path (Plane SR) are denoted $p_1$, $p_2$, and $p_{SR}$, respectively.

\[
|p|^2 = |w_{SR}p_{SR} + F_1w_1p_1 + F_2w_2p_2|^2 + (1 - F_1^2)|w_1p_1|^2 + (1 - F_2^2)|w_2p_2|^2
\]  
(394)

Figure 48
Definition of vertical propagation planes in case of a blocked direct propagation plane (top view).

If the lateral diffraction paths are far away from the direct propagation path the sound level from the three propagation paths shall be added incoherently but if the paths are very close to each other the contributions shall be added coherently. This is done according to Eq. (394). The weights $w_1$, $w_2$, and $w_{SR}$ depend on the correction for lateral diffractions ($\Delta L_4$ in Eq. (1) is equal to $20 \log(w)$) and $F_1$ and $F_2$ are coherence coefficients which accounts for the coherence between the lateral diffraction paths and the direct path.
Before determining the weights $w_{SR}$, $w_1$ and $w_2$ and the coherence coefficients $F_1$ and $F_2$ a number of variables used in the calculations have to be defined. Figure 49 defines the geometry used to calculate the variables for sound diffracted around the left vertical edge of the screen. $P_S$, $P_R$, and $P_1$ are the horizontal projections of the source, receiver and left edge. The variables $r_S$, $r_R$, $\theta_S$, $\theta_R$, $\beta$, $\rho$ in Figure 49 and other variables necessary for the calculation are determined by Eq. (395).

![Figure 49](image)

**Figure 49**

*Definition of parameters $\theta_S$, $\theta_R$, $\beta$, $r_S$ and $r_R$ to be used in the diffraction calculation and the transversal separation $\rho$ to be used in calculation of $F_c$.***
The weight $w_1$ can now be determined by Eq. (396) as the diffracted sound pressure relative to the free-field pressure ($p_0 = 1/r_{SR}$). The diffracted sound pressure is calculated by the auxiliary function $pwedge0$ for a non-reflecting wedge.

$$w_1 = \frac{pwedge0\left(f, \beta, \theta_S, \theta_R, \tau_{SR}, \tau_S, \tau_R, r_{SR}, r_S, r_R\right)}{p_0}$$

(396)

The coherence coefficients $F_1$ is calculated by Eq. (397) where $F_1$ is the coherence coefficient due to frequency band averaging (see Section 5.9.1) and $F_c$ is the coherence coefficient due to turbulence (see Section 5.9.3).

$$F_1(f) = F_{f\tau}(f, \tau_S + \tau_R - \tau_{SR})F_c\left(f, C_v^2, C_T^2, t_{mean}, \rho, r_{SR}\right)$$

(397)

The weight $w_2$ and the coherence coefficient $F_2$ corresponding to the contribution of sound diffracted around the right vertical edge of the screen can be calculated in a similar manner with the only alteration that $P_1$ has to be replaced by $P_2$.

Now $w_{SR}$ has to be determined by Eq. (398).
When the screen length becomes 0 the method described above will produce a result identical to the result obtained when ignoring the screen.

In the subsidiary case of unblocked direct propagation and the screen left of the source-receiver line, the sound pressure is calculated for the three vertical propagation planes defined in Figure 50. \( P_1 \) is the more remote of the two edges in the sense that it is the edge giving the largest sound pressure reduction. Plane SR is the direct propagation plane from the source to the receiver and Plane 1 and Plane 2 are defined as the lateral propagation paths around the left and the right edge of the screen. Plane 1 is passing just outside the screen so that the screen is not included in the lateral propagation parameters while plane 2 includes the screen. The corresponding sound pressures are denoted \( p_{SR} \), \( p_1 \) and \( p_2 \).

\[
w_{SR} = -F_1 w_1 - F_2 w_2 + \sqrt{1 - w_1^2 - w_2^2 + (F_1 w_1)^2 + (F_2 w_2)^2}
\]  

(398)

Figure 50
Definition of vertical propagation planes in case of an unblocked direct propagation plane (top view).

The sound pressure level for the unblocked case is also calculated by Eq. (394) but in this case the weights \( w_1 \) are in the same way calculated by Eq. (396) whereas \( w_{SR} \) are calculated by Eq.(399). The input variables of the function \( pwedge0 \) correspond to edge \( P_2 \).

\[
w_{SR} = 1 - \frac{pwedge0(f, \beta, \theta_s, \theta_R, \tau_{SR}, \tau_s, \tau_R, r_{SR}, r_s, r_R)}{p_0}
\]  

(399)
Finally, $w_2$ is calculated by Eq. (400)

$$w_2 = -F_1 w_1 - F_2 w_{SR} + \sqrt{1 - w_1^2 - w_{SR}^2 + (F_1 w_1)^2 + (F_2 w_{SR})^2}$$  \hspace{1cm} (400)

The same principle is used if the screen is right of the source-receiver line and $P_1$ is again defined as the more remote of the two edges in the sense that it is the edge giving the largest sound pressure reduction.

If the uncertainties introduced by using the incoherent summation ($F_1 = F_2 = 0$) can be accepted in cases where one of the vertical screen edges are close to the direct propagation plane it may be considered to apply this simplification.

Lateral diffraction can normally be ignored in case of moving sources due to the averaging caused by the movement.
Annex F

Solution of Integral in Eq. (19)

The average sound speed \( \bar{c} \) between the heights \( h_s \) and \( h_R \) is determined by Eq. (19). The equation contains an integral which is solved as shown below in this Annex. In the solution it is assumed that the vertical sound speed profile is defined by Eq. (2).

\[
\bar{c} = \frac{1}{h_R - h_s} \int_{h_s}^{h_R} \left( A \ln \left( \frac{z}{z_0} + 1 \right) + Bz + C \right) dz
\]  

Eq. (401) can divided into three integral terms as shown in Eq. (402).

\[
\bar{c} = \frac{1}{h_R - h_s} \int_{h_s}^{h_R} A \ln \left( \frac{z}{z_0} + 1 \right) dz + \frac{1}{h_R - h_s} \int_{h_s}^{h_R} Bz \, dz + \frac{1}{h_R - h_s} \int_{h_s}^{h_R} C \, dz
\]  

Each term is then solved as shown in Eq. (403).

\[
\bar{c} = A \frac{z_0}{h_R - h_s} \left( \frac{h_R}{z_0} + 1 \right) \left( \ln \left( \frac{h_R}{z_0} + 1 \right) - 1 \right) - \left( \frac{h_s}{z_0} + 1 \right) \left( \ln \left( \frac{h_s}{z_0} + 1 \right) - 1 \right)
\]

\[+ \frac{B}{2} (h_R - h_s) + C \]
